## **EXECUTIVE SUMMARY**

*Environmental Resources Management Australia Pty Ltd (ERM) was commissioned by Delta Electricity to undertake a Stage 2 Environmental Site Assessment (Stage 2 ESA) at Vales Point Power Station (herein referred to as the "Site") in accordance with the work scope presented in the Preliminary Environmental Site Assessment (PESA; ERM Reference 0227637RP01) prepared by ERM.*

*The primary objective for the Stage 2 ESA was to develop a baseline of environmental conditions at the Site, as at or near the time of the sale of the Site. Data obtained during completion of this Stage 2 ESA may also be used to inform future management of contamination at the Site.*

### **Investigation Methodology**

*To achieve the stated objectives, ERM collected soil, sediment, surface water and groundwater samples and submitted the samples to environmental laboratories for analysis of Constituents of Potential Concern (COPCs). A Conceptual Site Model (CSM) developed for the Site during the PESA was further refined and the analytical data was compared against published environmental screening values to assess potential risks to human health and the environment.*

*The following conclusions were made based on the data collected during the investigation.*

### **Investigation Outcomes**

- The key impacts identified included benzene in groundwater in the Vehicle Refuelling Area and downgradient of the Asbestos Landfills, PFOS (a chemical associated with firefighting foams) in groundwater around the boundary of the former A Station Demolition Area and the Chlorine Plant and Total Recoverable Hydrocarbons (TRH), benzo(a)pyrene, asbestos and metals in individual soil samples across the Site.*
- Selenium concentrations above adopted screening values were also identified in sediment samples collected from within Wyee Creek and Mannering Lake. It is considered likely that discharges from the Ash Dam, potentially including licensed discharges, runoff and groundwater flow have partially contributed to these impacts. Other potential sources within the catchment include mines, other power stations and other industries. The selenium concentrations identified in the current assessment were of the same order of magnitude as those identified in historic investigations suggesting that, as a result of changes to the management of discharges from the Ash Dam, the selenium load in Wyee Creek and Mannering Bay sediments has not increased significantly in recent years.*
- TRH and chlorinated hydrocarbons were reported in groundwater samples collected around the boundary of former A Station Demolition Area. The former A Station area could not be investigated directly due to ongoing demolition work and thus a potential data gap exists in this area.*

- *Various metals were identified at concentrations in excess of the adopted screening values across the Site. Where metals were identified above background concentrations, impact generally appears to be localised in distinct areas of the Site. The Ash Dam and Coal Storage Area, where the creation of Acid Sulfate Soil (ASS) conditions through the disturbance of alluvial sediments, historical and current underground coal mining works and/or the long term storage of waste ash materials and coal may have contributed to the observed metal impacts in groundwater. Acidic groundwater conditions in the vicinity of the Vehicle Refuelling Area also appear to have contributed to the presence of elevated metal concentrations in groundwater in that part of the Site.*
- *Fly-tipped waste was identified on the soil surface on the eastern boundary of the Wyee Rail Coal Unloader Area in the vicinity of the publicly accessible roadway.*

### ***Human Health and Environmental Risks***

- *With the exception of the selenium impacts identified in sediment (see below), the impacts identified in soil and groundwater at the sites are generally unlikely to represent a significant risk to human health and/or the environment given appropriate ongoing management based on the current and continued use of the Site as a Power Station.*
- *The selenium concentrations measured in Wyee Creek and Mannering Bay have the potential to adversely affect marine organisms in these areas. ERM understands that elevated selenium concentrations have previously been measured in fish collected from Mannering Bay and that the NSW EPA has previously been made aware of these impacts. Signage has been posted along Rutleys Road warning the public about the potential health risks associated with the long-term consumption of fish from this area.*
- *Licensed groundwater bores are not present in the immediate vicinity of the Ash Dam, but rural residential and residential communities are located immediately to the north, west and south. If the extraction of groundwater for potable, domestic, stock watering or commercial purposes was to occur in these areas in the future, the elevated metal concentrations in groundwater may be associated with risks to human health or livestock. It is recommended that this issue is raised with the NSW EPA when discussing the next scheduled deliverable associated with Pollution Reduction Program (PRP) being implemented in the Ash Dam area. It is suggested that the NSW EPA should manage ongoing communications on this issue, given the range of potential sources of metals in groundwater in this area and potential for the wider distribution of metals in groundwater.*
- *Asbestos was detected in individual shallow soil samples collected from bare ground within the Transformer Area, Chlorine Plant and around the boundaries of the Asbestos Landfill at concentrations in excess of the adopted human health screening values. All of these areas of asbestos impact may represent a health risk if Site employees were to come into contact with them. ERM understands that Delta has recorded these sites in its Asbestos Register and that these impacts shall be managed in accordance with Delta's existing asbestos management procedures.*

**Site Management and Remediation Requirements**

*Contamination issues that may require material management, remediation or further investigation, based on the current and continued use of the Site as a Power Station include the metals impacts in groundwater in the vicinity of the Ash Dam. These metal impacts in the vicinity of the Ash Dam are currently managed by Delta but this is an ongoing issue which could, in a worst case scenario, be material. Estimates for ongoing costs have not been made, as these costs will be dependent on outcome of the Pollution Reduction Program (PRP) currently in place within the Ash Dam area and ongoing discussions with NSW EPA. It is also noted that elevated background metal concentrations are present in the area and that the potential exists for inputs from current and historic mining activities and other potential sources to be material.*

*It is noted that conducting intrusive investigations within the B Station, Transformer Area and Former A Station demolition Area was not possible, due to the health and safety issues associated with demolition works and the presence of underground services in these areas. Further assessment may be required to identify unidentified soil and groundwater impacts within these areas if the land use of the Site was to change in the future.*

**Requirements under the Contaminated Land Management (CLM) Act 1997**

*ERM considers that NSW EPA would most likely continue to manage the metals in groundwater in the vicinity of the Ash Dam under the POEO Act (1997) via the Site Environmental Protection License (EPL). The Vales Point EPL includes the requirement for monthly groundwater monitoring in the vicinity of the Ash Dam throughout 2014. It is recommended that Delta include groundwater results from within the Ash Dam Area in the next scheduled report to the NSW EPA.*

*It is recommended that the NSW EPA is notified regarding the benzene concentrations measured in excess of the adopted human health (drinking water) screening levels in the Vehicle Refuelling Area and Asbestos Landfills. On the basis that the identified benzene impacts do not appear to be migrating offsite, it is considered unlikely in ERM's opinion that these impacts would be considered significant enough to warrant regulation by the NSW EPA.*

## 1 INTRODUCTION

On 24 November 2011, the New South Wales (NSW) Government announced that it would divest certain State-owned electricity generation assets. In order to support the sale of electricity generation assets owned and operated by Delta Electricity (a State Owned Corporation), Environmental Resources Management Australia Pty Ltd (ERM) were commissioned to undertake a Stage 2 Environmental Site Assessment (Stage 2 ESA) at Vales Point Power Station.

Vales Point Power Station, herein referred to as “the Site”, is situated adjacent to the southern shore of Lake Macquarie, near the township of Mannering Park, approximately 35 km south of Newcastle, NSW. A Site location plan is presented as *Figure 1 of Annex A*. The general Site layout is presented in *Figure 2 and Figure 3 of Annex A*.

The works detailed herein were completed in accordance with the work scope presented in the *Preliminary Environmental Site Assessment (PESA)* (ERM, 2014).

### 1.1 OBJECTIVES

The primary objective for the Stage 2 ESA was to gather soil, sediment, surface water and groundwater data in order to develop a baseline assessment of environmental conditions at the Site and within surrounding receiving environments (including sediment and surface water samples from Wyee Creek and Lake Macquarie), as at or near the time of the proposed transaction. Data obtained during completion of the Stage 2 ESA may also be used to inform future management of contamination issues both at the Site and in relation to the relevant receiving environments.

### 1.2 APPROACH AND SCOPE OF WORK

The adopted approach and scope of works for the Stage 2 ESA works comprised the following general tasks, in accordance with the requirements set out in the Sampling Analysis and Quality Plan (SAQP) defined in *Annex G* of the *PESA* (ERM, 2014):

#### *Preliminaries*

- preparation of a site-specific Health and Safety Plan (HASP) and Environmental Management Plan (EMP);
- assessment of whether suitable monitoring wells exist at the Site, and whether they can be sampled as part of this investigation;

- identification of areas and constituents of potential concern additional to those identified during the *PESA* (ERM, 2014) ;
- revision and amendment of the *SAQP* (ERM, 2014), as necessary;
- engagement of subcontractors including underground utility locators, drillers, laboratories and surveyors;
- scheduling of Site works with Delta Electricity; and
- completion of site-specific inductions and permitting.

*Site Works*

- ground-truthing of proposed sampling locations including clearance of underground services as noted below;
- identification of above and below ground services in the vicinity of drilling locations by reviewing publically available Dial Before You Dig (DBYD) plans and site engineering drawings, and engaging suitably qualified underground service locators;
- intrusive drilling works and environmental sampling, including soil, groundwater, sediment and surface water sampling, in accordance with the requirements of the *SAQP* (ERM, 2014);
- laboratory analysis of selected soil, groundwater, sediment and surface water samples for particular constituents of potential concern (COPC) in accordance with the requirements of the *PESA* (ERM, 2014) and *SAQP* (ERM, 2014) and as outlined in *Section 4.8*; and
- the survey of newly installed and existing monitoring wells by a registered surveyor to Australian Height Datum (AHD) and Map Grid of Australia (MGA) coordinates.

An additional round of groundwater sampling to aid in delineation of any impact identified in the original round of groundwater sampling.

*Reporting*

- preparation and submission of weekly progress reports to Delta Electricity; and;
- preparation and submission of this Stage 2 ESA report at the completion of works.

### 1.3 MATERIALITY THRESHOLD

For the purposes of this report, a consistent approach regarding the materiality of a contamination issue has been adopted to that utilised in the *PESA* (ERM, 2014) which was as follows:

- ERM adopted a materiality threshold of AUD 0.5 M (+ GST if applicable) per contamination source;
- material costs are those costs for that item to meet relevant requirements of NSW Environment Protection Authority (EPA) under its current land use to remediate or manage the contamination issue. Remediation or management includes additional assessment, environmental monitoring, management, containment or other remediation measures; and
- any issue that ERM considers could have the potential to lead to prosecution by the regulatory authorities that could lead to significant business disruption or reputational impact has been considered material.

### 1.4 REPORT STRUCTURE

This Stage 2 ESA report has been prepared in general accordance with the NSW EPA *Guidelines for Consultants Reporting on Contaminated Sites* (EPA, 1997), as follows:

- *Section 1* - Introduction, background, objectives and scope of works;
- *Section 2* - Site setting including a summary of the Site history and Site conditions;
- *Section 3* - Data Quality Objectives (DQOs) for the works conducted;
- *Section 4* - Sampling and works methodologies for completing the investigation;
- *Section 5* - Results of the Stage 2 ESA works and Site-specific discussions and recommendations; and
- *Section 6* - Overall Discussion
- *Section 7* - Conclusions.

A full list of all references is also appended to this report.

## 1.5

*LIMITATIONS*

The findings of this report are based on the client-approved *SAQP* within the PESA (ERM, 2014) and the scope of work summarised in *Section 1.2* of this report. ERM performed the services in a manner consistent with the normal level of care and expertise exercised by members of the environmental assessment profession. No warranties express or implied, are made.

Although normal standards of professional practice have been applied, the absence of any identified hazardous or toxic materials on the subject Site should not be interpreted as a guarantee that such materials do not exist on the Site.

This assessment is based on Site inspections conducted by ERM personnel, sampling and analyses described in the report, and information provided by people with knowledge of Site conditions.

All conclusions and recommendations made in the report are the professional opinions of the ERM personnel involved with the project and, while normal checking of the accuracy of data has been conducted, ERM assumes no responsibility or liability for errors in data obtained from regulatory agencies or any other external sources, nor from occurrences outside the scope of this project.

ERM is not engaged in environmental assessment and reporting for the purpose of advertising sales promoting, or endorsement of any client interests, including raising investment capital, recommending investment decisions, or other publicity purposes. The client acknowledges that this report is for the exclusive use of the client, its representatives and advisors and any investors, lenders, underwriters and financiers who agree to execute a reliance letter, and the client agrees that ERM's report or correspondences will not be, except as set forth herein, used or reproduced in full or in parts for such promotional purposes, and may not be used or relied upon in any prospectus or offering circular.

## 2 BACKGROUND

### 2.1 SITE SETTING

#### 2.1.1 Site Identification

The Site location and the Site boundaries are presented in *Figures 1* and *2* of *Annex A*. A summary of site identification information is presented in *Table 2.1*.

**Table 2.1 Site Identification Details**

Site Detail	Description
Site Name	Vales Point Power Station
Site Location	Vales Road, Mannering Park, NSW
Coordinates	33°09'58"S and 151°32'34"E.
Area	Total area approximately 1700 hectares (Ha) <sup>1</sup> Operational area approximately 180 Ha
Owner	Delta Electricity (State Owned Corporation)
Local Government	Wyong Shire Council and Lake Macquarie City Council
Title Information <sup>2</sup>	The Site is sub-divided into 133 Lots within 51 separate Deposited Plans.
Zoning <sup>3</sup>	Under the Wyong Local Environmental Plan (LEP) 2012, most of the Site including the operational area, is zoned SP2 - Electricity Generating Works. Small portions of the Site, immediately south of Wyee Bay, are zoned E2 - Environmental Conservation. Areas designated W2 - Recreational Waterways are also located along the shoreline immediately north east and north west of the Site.  Under the Lake Macquarie LEP (2004), most of the Site is zoned 4(1) - Industrial (core). Areas on the periphery of the Site are zoned 9 - Natural Resources. Areas immediately surrounding Mannering Lake are zoned 7(1 and 2) - Conservation (primary and secondary) and 9 - Natural Resources. Properties zoned 1(1) - Rural were also located south west of Mannering Lake

1. Includes water canals, but excludes areas for associated mines.  
2. A full list of relevant title information is presented in *Annex C* of the *PESA* (ERM, 2014).  
3. Detailed zoning plans are presented in *Annex D* of the *PESA* (ERM, 2014).

A number of parcels of land within the Delta Electricity property boundaries are subject to mining leases and have been excluded from the Stage 2 scope of works. These areas have been considered to be potential offsite sources of contamination for the purposes of this assessment. These areas include;

- the Mandalong Mine delivery infrastructure adjacent to the Wyee rail coal unloader;
- the Mannering Colliery; and
- the Chain Valley Colliery.

These areas are detailed in *Figure 2* of *Annex A*.

A Microfiltration (MF) Plant is located at the Mannering Park Sewage Treatment Plant, immediately to the east of the Vales Point Site. It is understood that the MF Plant site is leased from Wyong Shire Council but that Delta Electricity owns the plant and equipment. This area has also been excluded from the Stage 2 scope of works.

### 2.1.2 *Site Features*

The Site is composed of the following key features:

- Vales Point Power Station and associated infrastructure. Vales Point Power Station was built in the 1960s as a four-unit station (the former A Station). These generating units were decommissioned in the late 1980s and the aboveground structures were being demolished at the time of this investigation. Vales Point now operates two 660 MW generating units, with a total generating capacity of 1320 MW of electricity (B Station);
- ash dam and associated pipelines for ash slurry and return water;
- coal storage area, including a truck wash down area, refuelling and maintenance area and settling ponds;
- conveyors transporting coal from nearby mines to the Site;
- waste disposal areas, including six former asbestos dumps;
- several water treatment systems, including a demineralised water plant, a chlorine plant, a reverse osmosis plant and an oil and grit trap;
- buffer lands surrounding the infrastructure described above, this includes State Environmental Planning Policy (SEPP) 14 listed wetlands to the north and west of the Site;
- the Wyee Rail coal unloader and Rail to Vales Point conveyor system (referred to as RV conveyor system, located to the north west of the operational area);
- a fly ash loading plant, owned and operated by Adelaide Brighton Cement (trading as Morgan Ash), to the south east of the operational area.

For the purpose of this assessment, the Site has been divided into 21 individual Areas of Environmental Concern (AECs), according to usage and the presence of potential sources of contamination, as follows;

- VA - B Station Operational Area;
- VB - former A Station Demolition Area;
- VC - Transformer Area;

- VD – Main Dangerous Good Store;
- VE – Contaminated Water Treatment Plant;
- VF – Waste Oil Storage Area;
- VG – Fuel Oil Installation;
- VH- Vehicle Refuelling Area;
- VI – Water Treatment Area;
- VJ – Coal Storage Area;
- VK – Mobile Plant Area;
- VL – Sewage Treatment Plant;
- VM – Chlorine Plant;
- VN – Wye Rail Coal Unloader;
- VO – Ash Dam;
- VP – Asbestos Landfills;
- VQ – Dust Line;
- VR – Wye Creek and Lake Macquarie Sediments and Surface Waters;
- VS – TransGrid Switchyard;
- VT – Fly Ash Plant
- VU – Site Buffers and Boundaries

The locations of the AECs are illustrated in *Figures 6.1 to 6.6 of Annex A*.

### **2.1.3** *Surrounding Environment*

The Site is surrounded by residential properties, remnant bushland and industrial properties, as well as waterways and areas of protected wetlands.

Key industrial uses in the area include:

- Chain Valley Colliery, approximately 750 m south east of the operational area;

- Mannering Colliery, approximately 1.8 km south of the operational area;
- the Mandalong coal mine delivery infrastructure located approximately 5 km to the north west; and
- a municipal sewage treatment plant, located approximately 1 km south west of the operational area, or immediately west of the Site boundary.

The closest residential areas to the Site include:

- Mannering Park, located north of the Site approximately 600 m from the operational area;
- Doyalson East, located approximately 300 m south of the Ash Dam
- Kingfisher Shores, approximately 2 km south east of the operational area and 1.6 km north east of the Ash Dam; and
- Wyee, located approximately 150 m east of the Ash Dam; and
- Wyee Point, located directly to the east of the north western leased mine area.

Rural residential properties are also located immediately to the north of the Ash Dam area and to the south of the Ash Dam area along Wyee Rd.

The Site is surrounded by areas of remnant bushland. Ecologically significant areas or recreational areas of note surrounding the Site include:

- State Environmental Planning Policy (SEPP) No. 14 protected wetlands located along the northern and eastern perimeter of Mannering Lake. The wetlands located on the eastern perimeter of Mannering Lake are also located within approximately 100 m of the Ash Dam toe drain system;
- SEPP 14 protected wetlands are also located on either side of Wyee Creek, approximately 1 km north of the Ash Dam;
- Tom Barney Oval is located immediately to the south west of the operational area. Based on discussions with the Site Environmental Officer, this oval is occasionally booked out for sporting events, and is regularly accessed by the public;
- Chain Valley Bay Reserve is located 1 km south of the operational area. Public use of this area appeared to be limited based on the lack of amenities and cleared areas; and
- Recreational fishing and boating activities are also undertaken in Lake Macquarie, including Mannering Bay, Chain Valley Bay and Wyee Bay.

## 2.2 ENVIRONMENTAL SETTING

### 2.2.1 Topography

The Site is located on the coast of Lake Macquarie, in between Wyee Bay and Chain Valley Bay. The operational area of the Site is generally flat and lies at an average elevation of approximately 3 m Australian Height Datum (AHD).

A ridge lies along the eastern boundary of the operational area and the Fuel Oil Installation, Fly Ash Plant, Coal Storage Area and Mobile Plant Area are located at between approximately 8 and 20 m AHD to the east and south of this ridge. To the west of the operational area the Site slopes upwards towards the Sewage Treatment Plant, at an elevation of approximately 10 m AHD.

The Ash Dam has been constructed within a natural valley, from the ridge to the south orientated to the north east, towards Mannering Bay, with a slight incline towards the north west, where it discharges into Wyee Creek.

The Wyee Rail Coal Unloader area lies at between approximately 18 and 50 m AHD, with a slope towards Lake Macquarie in the east.

### 2.2.2 Hydrology

The Site is located in the Lake Macquarie catchment area, with Lake Macquarie identified as the main local hydrological feature. Local waterways can be summarised as follows:

- Chain Valley Bay, located immediately to the north east of the Site;
- Mannering Bay with Wyee Bay immediately beyond, located immediately north of the Site;
- the Vales Point cooling water canal, which enters the Site at Chain Valley Bay and exits the Site at Wyee Bay;
- Chain Valley Retention Pond (also known as Lake Rodham), located approximately 300 m north east of the operational area, forms a part of the Site contaminated water management system;
- Wyee Creek and the Wyee Creek diversion channel is located along the north western site boundary and function as part of the Ash Dam overflow system;
- Mannering Lake, which forms part of the Vales Point Ash Dam;
- three settling ponds associated with the sewage treatment works on Site, located 500 m north west of the operational area; and

- five settling ponds associated with the coal storage area, approximately 700 m south west of the operational area.

The Vales Point Power Station uses coal as the fuel source to generate electricity and as a consequence produces a significant amount of by-product ash including furnace ash and fly ash. A large proportion of the ash which is produced from the Power Station is transported by wet sluicing via a pipeline to the Ash Dam. The disposal of ash within the Ash Dam is approved under the current Vales Point Power Station Environment Protection Licence (EPL) (Clause P1.3 of EPL 761).

Operational use of the dams and ponds listed above are outlined in the PESA (ERM, 2014).

In terms of surface water catchments on the Site, the topography indicates that surface water in the operational area of the Site and its surrounds, including the Fly Ash Plant, Fuel Oil Installation, Coal Storage Area and Sewage Treatment Plant generally flows to the north east, towards Lake Macquarie. Surface water within the operational area of the Site is channelled into a stormwater system that also discharges into Lake Macquarie via Lake Rodham.

The Ash Dam is located within a separate surface water catchment, which drains towards Lake Mannering to the north and Wyee Creek to the west. The Wyee Rail Coal Unloader area drains towards Lake Macquarie to the east.

### 2.2.3

#### *Geology*

##### *Regional Geology*

Based on a review of the *Gosford – Lake Macquarie 1:100 000 Provisional Geology Sheet* (Geological Survey of New South Wales, 2003), the Site operational area, including coal storage facility is located on the late Permian to early Triassic Munmorah Conglomerate formation of the Clifton Subgroup, Narrabeen Group. The Munmorah Conglomerate formation is comprised of conglomerate and medium to coarse-grained sandstone with minor siltstone and claystone (Geoscience Australia). The area comprising the Ash Dam is indicated as *man-made fill*, which refers to the construction of the ash dam, which is also underlain by the Munmorah Conglomerate. Areas immediately surrounding Mannering Bay and Wyee Bay tributaries are located on Quaternary sediments comprised of gravel and sand. The geology map for the area further indicates the presence of a number of north-west to south-east trending dykes that have intruded into the Munmorah Conglomerate.

These dykes have a regional spacing of approximately 0.2 km to 2 km with strike lengths in excess of 2km in the study area. The geology map further indicates the presence of a north-west to south-east striking fault with a south-westerly dip in the southern section of the ash dam.

Extensive underground coal mining activities are present in the region with target coal seams occurring in the late Permian Newcastle Coal Measures (a predominantly sandstone and coal sequence with lesser siltstone) that underlie the Clifton Subgroup. The Mannering Colliery, which undermined sections of the Site, targets the Great Northern and Fassifern coal seams. The Great Northern seam, which overlies the Fassifern seam, is located between approximately 140 to 155 metres below ground level (m bgl) in the area (Centennial Coal, 2009).

The local geology, as encountered during the drilling program undertaken as part of Stage 2 ESA, is discussed further in *Section 5.1* of this report.

The GHD (2012) *Delta Coast Land Management Manual* identified that there is a high risk of Potential Acid Sulfate Soil (PASS) conditions being present in a number of areas of the Site, including areas to the north of the Ash Dam and north east of the Power Block. A detailed delineation of PASS conditions within the Site is outside the scope of this assessment as they are a naturally occurring geological condition and unrelated to the operations on the Site. The presence of actual acidic ground conditions (which may have been created via the disturbance and oxidation of soils or modification of hydrogeological conditions) has been assessed via field observations (e.g. presence of jarosite) and the measurement of field parameters including pH and ORP during groundwater monitoring (refer to *Section 4.4*).

#### 2.2.4

#### *Hydrogeology*

##### *Regional Hydrogeology*

From a hydrogeology perspective, the sedimentary deposits can be categorised into the following units:

- Moderately permeable Quaternary sediments. While the geological map indicates that the sediments consist predominantly of sand and gravel, the available information from the intrusive works conducted at the Site indicate that there is a relatively high degree of fine grained material within the sediments (which have generally been described as sandy clay) which would constrain the permeability of the sediments.
- Moderate to relatively highly permeable conglomerate and sandstone, with permeability largely governed by the degree of fracturing in the conglomerate and sandstone.
- Low permeability siltstone and claystone.

- Moderate to relatively highly permeable coal seams within the Newcastle Coal Measures, with permeability governed by the degree of cleat development and fracturing within the coal seams.

Regional groundwater flow is expected to be towards Lake Macquarie, which is generally located to the north and north east of the Site. Temporal and localised variations in the direction of groundwater flow is considered likely given the low lying nature of the area and the presence of tidally influenced lakes, and the effects of increased hydraulic head created by the wet disposal ash dam.

The presence of dykes that have intruded into the Munmorah Conglomerate further present potential localised barriers to groundwater flow.

Details of hydrogeological conditions encountered during this Stage 2 ESA are summarised in *Section 5.2*.

### 2.2.5 *Groundwater Use*

The alluvial aquifers and shallow conglomerate and sandstone aquifers are the prime aquifers used in the region for stock and domestic supplies. Mining activities have extensively impacted the deep coal seam aquifers in the region, with extensive depressurisation of the coal seams having taken place in the region. Use of the coal seams aquifers for stock and domestic purposes are further restricted by the general high salinity of groundwater within the coal seams (Centennial Coal, 2009).

The NSW Natural Resource Atlas online bore register (accessed 17 December 2013) (NSW Government) identifies six groundwater bores within a 5 km radius of the Vales Point Power Station.

One groundwater bore, located approximately 700 m north of the Site in Mannering Park, is reportedly used for domestic purposes. The Standing Water Level (SWL) was recorded in this well at 5.5 m bgl. One groundwater bore, located approximately 1 km south west of the Power Station operational area and 600 m north of the Ash Dam is reportedly used for stock (poultry) watering purposes. The remaining four groundwater bores were reported to have been installed for test or monitoring purposes, with SWL recorded in three of these bores at 6 m bgl.

## 2.3 *SITE OPERATIONAL HISTORY*

Construction of the Power Station commenced in 1963 with construction of A Station, and B Station was completed in the early 1980s. Ancillary additions have been made to the Power Station since construction was completed in the early 1980s, including the construction of the sewage treatment area and additional settlement ponds. At the time of completion of the Stage 2 ESA, the A Station buildings were undergoing demolition and removal offsite.

Further detailed information regarding the history and operation of the Site, including historical aerial photographs, zoning and environmental approvals, licenses and management is presented in the *PESA* (ERM, 2014).

## 2.4 NSW EPA CONTAMINATED SITE RECORDS

The *Contaminated Land Management Record of Notices* is a public database of information regarding significantly contaminated land in NSW and is managed by the NSW EPA under the *Contaminated Land Management Act 1997* (CLM Act 1997).

At the time of this assessment, the Site had not been notified to the NSW EPA as being potentially contaminated. As part of the *Preliminary Baseline Contamination Assessment & Duty to Report Contamination Central Coast Region - Vales Point Power Station, Munmorah Power Station And Colongra Gas Turbine* (GHD, 2012) concluded that '*data reviewed as part of this baseline assessment does not indicate that notification is required*'. The following nearby properties were identified on the *NSW EPA List of Contaminated Lands Notified to the EPA* as properties where it has yet to be determined whether contamination is significant enough to warrant regulation under the *CLM Act 1997*:

- Mannering Colliery, Rutleys Road, Doyalson. Listed as EPA Site Management Class A, which indicated that assessment of the Site by the EPA was still in progress.
- Mannering Park Mini Mart, 70 Vales Road, Mannering Park. This property was identified as a service station. Listed as EPA Site Management Class B, which indicated that initial assessment of the Site by the EPA was still in progress.
- Parkview General Store, 2 Vales Road, Mannering Park. This property was identified as a former service station. Listed as EPA Site Management Class B, which indicated that initial assessment of the Site by the EPA was still in progress.

## 2.5 PREVIOUS ENVIRONMENTAL INVESTIGATIONS

The Site has undergone a limited number of historical intrusive soil and groundwater assessments which are described in the *PESA* (ERM, 2014). Works were generally completed to achieve compliance with EPL requirements and Underground Petroleum Storage System (UPSS) regulations.

Previous environmental investigations reviewed included:

- groundwater monitoring undertaken down-gradient of the ash dam by Aurecon in 2013. It is understood that additional groundwater monitoring wells were being installed by Aurecon in this area in late December 2013. The installation of these groundwater wells is part of an additional investigation of elevated metals concentrations in groundwater undertaken by Delta to comply with the Pollution Reduction Programme (PRP) notice on the POEO licence.
- surface water monitoring associated with licensed discharges as a condition of EPL 761;
- investigations associated with the Protection of the Environment Operations (Underground Petroleum Storage Systems) Regulation 2008 (UPSS Regulations) including routine groundwater monitoring by David Lane Associates and Douglas Partners between 2010 and 2013; and
- a preliminary (non-intrusive) baseline assessment of contamination issues (GHD, 2012). This included a preliminary contamination risk ranking, recommendations for contamination assessment, remediation or site management measures and a summary of Delta Electricity's obligations to report under the CLM Act 1997 based on the available information for the Site. The GHD (2012) report also identifies 14 areas of environmental concern (AECs) at the Site.

## 2.6

### *POTENTIAL AND KNOWN SOURCES OF CONTAMINATION*

Potential AECs were identified in the *PESA* (ERM, 2014) based upon current operations, in conjunction with a review of chemical and waste inventories, spill and incident information, a review of the limited soil and groundwater investigations completed to date and discussions with Delta Electricity staff.

Potential and actual AECs identified at the Site are presented in *Table 2.2*.

**Table 2.2** *Summary of Areas of Environmental Concern*

<b>I.D.</b>	<b>Name</b>	<b>Description</b>
VA	B Station Power Block	The primary source of potential contamination identified is potential leaks or spills of lubricating oil and fuel at various points which may migrate through cracks in concrete or via damaged drains. A major fire event fire occurred in the 5A Air Heater in 2011 and Aqueous Film Forming Foam (AFFF) constituents (used in firefighting foams) are therefore potential COPCs. The network of drains which runs beneath the power block may also be a source of impact.
VB	Former A Station	The primary sources of potential contamination within the former A Station area are associated with historic lubricating oil and fuel leaks at various points.
VC	Transformer Area	Potential for PCBs associated with transformer operation and oil storage in ASTs. In 2006 the Vales Point Unit 6A 330/22kV Generator Transformer failed, resulting in an explosion and fire. Aqueous Film Forming Foam (AFFF) constituents are therefore potential COPCs.
VD	Main Dangerous Goods Store	Storage of flammable liquids, oils, lubricants, greases and corrosive liquids.
VE	Contaminated Water Treatment Plant	Treatment of the water captured by the contaminated water drain system at the Power Station. Water entering the facility could contain a range of potential contaminants including fuels, chemicals, coal and ash.
VF	Waste Oil Storage Area	Storage of waste oil in drums and containers and oily rags.
VG	Fuel Oil Installation	Storage of diesel in 2 ASTs.
VH	Vehicle Refuelling Depot	Underground Storage Tanks (USTs) (current and decommissioned) used to store unleaded petrol and diesel.
VI	Water Treatment Plant Area	Significant quantities of sulfuric acid, sodium hydroxide, hypochlorite, ammonia and ferric sulfate are stored in ASTs in this area.
VJ	Coal Storage Area	Leaching of contaminants from the coal stockpiled on open ground may affect groundwater. Dirty water from the truck washing facility and contaminated stormwater runoff.
VK	Mobile Plant Maintenance and Refuelling	Potential contamination sources include contaminated stormwater runoff from this area and leaks or spills of oils and solvents.
VL	Sewage Treatment Plant	Potential contamination sources associated with the sewage treatment plant include leakage from the sewage treatment systems, associated pipework or retention basin into the underlying soil or groundwater. Sewage can contain a variety of contaminants, including nitrates, metals, trace concentrations of toxic chemicals and salts.
VM	Chlorine Plant	The water treatment plant area is banded but potential damage to the bunds or bund linings surrounding some of the ASTs or corrosion of the associated pipework may have led to uncontrolled releases of chemicals to stormwater or directly to the subsurface via cracks or other preferential pathways. It is also noted that the transformer oil storage filtration building, associated with the TransGrid Switchyard is located immediately adjacent to the Chlorine Plant.

COMMERCIAL IN CONFIDENCE

I.D.	Name	Description
VN	Rail Coal Unloader Area and Coal Conveyors	Storage and transport of coal and coal wastes.
VO	Ash Dam	The Ash Dam receives ash from Vales Point via slurry pipelines and dirty water from the coal handling area and effluent pit in the Power Station. Prior to Munmorah Power Station ceasing operations, the Vales Point Ash Dam was also used for the storage of fly ash produced at Munmorah Power Station. Various other solid wastes are also directed to the Ash Dam in accordance with EPL 761.
VP	Asbestos Landfills	Six known dump sites are located within the catchment of the Ash Dam.
VQ	Dust Line	Aboveground dust pipeline transferring dust from the operational area of the Site and the Ash Dam contains asbestos.
VR	Sediments in Surrounding Waterways	Lake Macquarie sediments and surface water have been identified as a potential AEC due to the discharges that the Lake receives from the Power Station including cooling water, treated effluent, overflow and potential seepage from the Ash Dam, stormwater and groundwater
VS	TransGrid Switchyard	TransGrid Switchyard, although not operated by Delta Electricity, is a potential AEC due to the storage/use of transformer oil which may have historically contained PCBs. The Vales Point Fire Training Area is located adjacent to the TransGrid Switchyard
VT	Fly Ash Plant Area	Operations associated with the management of fly-ash by-products.
VU	Buffer Lands and Boundaries	General baseline conditions and offsite migration.

## 2.7 SENSITIVE RECEPTORS

The sensitive receptors identified in association with the Site include:

- indoor and outdoor human health receptors in the form of onsite and offsite workers;
- intrusive maintenance workers both on and offsite;
- offsite residential receptors, living in the vicinity of the operational area or Ash Dam;
- recreational users of Mannering Bay, Wyee Bay and Chain Valley Bay;
- recreational users of Tom Barney Oval;
- aquifers beneath the Site and nearby potable and stock watering wells; and
- ecological receptors, including those in the vegetated buffer lands and aquatic environments of Mannering Bay, Wyee Creek, Wyee Bay and Chain Valley Bay, including SEPP 14 protected wetlands along the northern and eastern perimeter of Mannering Lake, and either side of Wyee Creek.

Onsite water bodies that are used for operational purposes, including the Ash Dam, the cooling water canal and the various water retention, treatment and settling ponds, are not considered to be ecological receptors.

The *Delta Coast Land Management Manual* (GHD, 2012) provides information on the uses of the various areas of the Site, including operational areas (including those allocated for power generation activities, ash storage areas, coal conveyors, canals, pipelines and coal storage areas) and buffer lands. Within the buffer lands are areas of vegetation and decommissioned and operational coal mines. GHD (2012) indicates that threatened flora and fauna has been identified in the buffer lands surrounding the Ash Dam and the Wyee Rail Coal Unloader.

### 3 DATA QUALITY OBJECTIVES

Data quality objectives (DQOs) were developed to define the type and quality of data required to achieve the project objectives outlined in *Section 1.1* of this report. The DQOs have been prepared in line with the seven-step approach outlined in National Environment Protection (Assessment of Site Contamination) Measure 1999 (ASC NEPC, 2013), and with reference to relevant guidelines published by the NSW EPA, ANZECC/ARMCANZ, and NEPC.

The DQO process is validated, in part, by the Quality Assurance and Quality Control (QA/QC) procedures and assessment, summarised in *Section 5.5* and presented as *Annex F* of this report.

The seven steps of the DQO process, and how they were applied to this assessment, are presented in the following sections.

#### 3.1 STEP ONE: STATE THE PROBLEM

A statement of the problem is provided by the particular objectives of the assessment as stated in *Section 1.1*. Background information is provided by *Sections 1* and *2* of this report, and by the conceptual site model (CSM) which was initially developed as part of the *PESA* (ERM, 2014).

#### 3.2 STEP TWO: IDENTIFY THE DECISION

##### *Decision Statements*

The principal decision to be made is:

- Are there actual or potential material contamination issues relevant to the sale of the Vales Point Power Station?

Additional decisions to be made include:

- Is there sufficient data to provide an environmental baseline at the time of the transaction?
- What is the nature and extent of soil, surface water and groundwater impact on or beneath the Site?
- What is the nature and extent of sediment and surface water and impact to surrounding water bodies?
- Does the impact at the Site represent a risk to human health, based on the current and continued use of the site?

- Is the impact at the Site likely to warrant notification and / or regulation under the *NSW Contaminated Land Management Act, 1997*?
- Is material remediation likely to be required?

Adopted screening values which informed these decisions are identified below in *Section 4.10*.

### 3.3 *STEP THREE: IDENTIFY INPUTS TO DECISION*

The inputs required to make the above decisions are:

- existing relevant environmental data, taking into consideration the number and location of existing soil and groundwater sampling locations, the construction of existing groundwater monitoring wells and the date of the most recent sampling events;
- direct measurement of environmental variables including soil/sediment type, soil gas concentrations, odours, staining or other visual evidence of potential contamination, water strike, groundwater level and water quality parameters;
- collection and laboratory analysis of soil, groundwater, sediment and surface water samples for identified COPCs;
- field and laboratory QA/QC data; and
- comparison of data against adopted screening values (outlined in *Section 4.10*).

### 3.4 *STEP FOUR: DEFINE THE STUDY BOUNDARIES*

#### *Spatial Boundaries*

The Site location and description is provided in *Section 2*. Figures identifying the Site boundary and investigation areas are presented in *Annex A*. The investigation included the surface and subsurface soils as well as groundwater beneath the site but the vertical boundaries of the investigation were limited to the depth of borehole advancement.

#### *Temporal Boundaries*

Temporally, the study is intended to provide a baseline assessment of the nature and extent of contamination at the Site, and in relevant receiving environments, as at or near the time of completion of the proposed transaction to the extent practicable.

*Constraints within the Study Boundaries*

Constraints on the delivery of the objectives of the Stage 2 ESA program within the study boundaries included:

- location of underground or overhead services or infrastructure;
- the condition of existing monitoring wells; and
- access restrictions, such as flooded areas.

**3.5*****STEP FIVE: DEVELOP A DECISION RULE***

The DQOs were designed to facilitate the collection of adequate soil, sediment, surface water and groundwater data to address the decisions in Step 2 of the DQO process. Decision Rules were therefore developed both in relation to evaluating the nature and extent of soil, surface water and groundwater impact on or beneath the Site and the adequacy of the data set, as outlined herein.

**3.5.1*****Sample Locations***

Where these constraints were identified, boreholes and monitoring wells were moved (where possible to nearby locations) and where drilling was not feasible, surface soil samples were collected to assess direct contact pathways. Additionally monitoring wells that could not be successfully drilled to depth were converted to soil bores.

In areas which could not be accessed for drilling or where the abovementioned constraints prevented the installation of groundwater monitoring wells, monitoring wells were located around the perimeter of the inaccessible area where possible. The distribution of monitoring wells around the perimeter of AECs was then evaluated to assess whether it provided an understanding of groundwater conditions up-gradient and down-gradient to assess the potential extent of contamination and identify potential for migration of contaminants.

Deviations from the Stage 2 program were tracked during the course of the investigation via the weekly progress spreadsheet and were communicated to the relevant project stakeholders.

A summary of the investigation locations proposed and installed and evaluation of the adequacy of spatial coverage of the Site is presented in *Section 4.1* of this report.

### 3.5.2 *Field and Laboratory QA/QC*

The reliability of soil, sediment, surface water and groundwater data was assessed based on comparison with acceptable limits for field and laboratory QC samples outlined in relevant guidelines made or approved under the *CLM Act 1997*, including the *ASC NEPM* (NEPC, 2013).

In the event that acceptable QC limits were not met, the field observations of the samples were reviewed for obvious sources for the non-conformance (such as an error in sampling, preservation of sample(s) or heterogeneity of sample(s), etc.) If obvious sources of the non-conformance were not identified, liaison with the laboratories was undertaken to identify the issue that had given rise to the non-conformance.

In the event that acceptable QC limits were not met, the impact of these non-conformances was also evaluated in relation to adequacy of the data set facilitate the collection of adequate soil, sediment, surface water and groundwater data to address the decisions in Step 2 of the DQO process.

The acceptable limits on decision errors applied during the review of the results are discussed in *Section 3.6* and a summary of the QA/QC procedures is presented in *Section 4.9* and *Annex F* of this report.

### 3.5.3 *Screening Values*

Groundwater, sediment and surface water data, along with the maximum, minimum, mean, standard deviation and 95% upper confidence limit (UCL) of the mean concentration (if required) were compared to screening values to provide a screening value assessment of potential risks that may be associated with the SPR linkages that have been identified for this Site.

The adopted screening values have generally been sourced from guidelines made or approved under the *CLM Act 1997*, which includes the *ASC NEPM* (ASC NEPC, 2013). Where alternative sources have been utilised, appropriate justification has been provided. The specific assessment levels adopted are presented alongside the analytical data in the summary tables presented in *Tables 4a-u and 5a-u* of *Annex B*. The screening values are discussed in detail in *Section 4.10*.

Individual soil, groundwater, sediment and surface water data, along with the maximum, minimum, mean, standard deviation and 95% upper confidence limit (UCL) of the mean concentration (if required) were compared to adopted screening values.

Exceedance of adopted screening values does not necessarily indicate the requirement for remediation and/or a risk to human health or the environment. The approach to the screening of the data gathered in this assessment has generally been to initially adopt conservative assessment values. Any exceedances of these values have then been evaluated on a case by case basis, in light of the specific characteristics of the individual sample and the area of the Site from which the sample was collected. The extent of the impact, the potential for receptors to be exposed to the impact, and regulatory compliance was also considered.

If individual or 95% UCL concentrations exceeded the adopted screening values and these exceedances were evaluated to be associated with a potentially complete SPR linkage, these results were considered to be indicative of actual or potential material contamination issues relevant to the sale of the Site, as per DQO Step 2 (*Section 3.2*).

#### **3.5.4 *Appropriateness of Laboratory Limit of Reporting***

Comparison of the laboratory Limit of Reporting (LOR) to the screening values has been undertaken to confirm that the screening values are less than the laboratory LOR. In the event that the screening value is greater than the laboratory LOR, consideration has been given to the significance of this result, with specific reference to addressing the Decisions in Step 2 of the DQO process.

An evaluation of the screening values with reference to the laboratory LORs is provided in *Section 5.5*.

#### **3.6 *STEP SIX: SPECIFY LIMITS ON DECISION ERRORS***

The primary output from Step 6 of the DQO Process is a set of acceptance criteria that the collected data should achieve in order to minimise the possibility of either making a decision error or failing to keep uncertainty limits with acceptable levels (US EPA , 2006).

The acceptable limits on decision errors applied during the review of the results has been based on the Data Quality Indicators (DQIs) of Precision, Accuracy, Representativeness, Comparability and Completeness (PARCC) in accordance with (NHMRC and NRMCC, 2013) *National Environment Protection (Assessment of Site Contamination) Amendment Measure 2013, Schedule B3 - Guideline on Laboratory Analysis of Potentially Contaminated Soils*.

The potential for significant decision errors was also minimised by:

- completing a robust QA/QC assessment of the validation data and application of the probability that 95% of data will satisfy the DQIs, therefore a limit on the decision error would be 5% that a conclusive statement may be incorrect (see *Section 4.9*);
- assessing whether appropriate sampling and analytical density has been achieved for the purposes of providing a baseline of soil, sediment and groundwater conditions at the point of transaction (see *Section 4.1*); and
- ensuring that the screening values adopted were appropriate for the ongoing use of the site as a power generation facility (see *Section 4.10*).

### 3.7

#### ***STEP SEVEN: DEVELOP (OPTIMISE) THE PLAN FOR COMPLETING THE WORKS***

The DQOs have been developed based on a review of existing data and discussions with Delta Electricity. If data gathered during the assessment indicated that the objectives of the assessment programme were not being met, the sampling design (including sampling pattern, type of samples and analytes) was adjusted accordingly using feedback (where necessary) from project stakeholders.

## 4 INVESTIGATION METHODOLOGY

### 4.1 SAMPLING LOCATIONS

Based on a review of the available data, the most appropriate sampling design to achieve the stated project objectives was considered to be primarily based on a judgemental (targeted) sampling program, which provides good coverage of operational areas and minimal additional sampling undertaken to provide spatial coverage for low risk areas of the site (e.g. buffer lands) or to fill material data gaps within the CSM.

Given the scale of the site, different sampling densities were adopted based on estimated contamination risk and logistical constraints of different areas of the site. The sampling approach was generally in accordance with the NSW EPA *Sampling Design Guidelines* (NSW EPA, 1995) which does not recommend a minimum number of sampling points for sites larger than 5 ha. As recommended in these guidelines, the Site has been divided into smaller areas of concern based on a review of historical activities and identified potentially contaminating activities. Judgemental sampling was adopted to target potential sources for all AECs.

It is noted that intrusive investigations were limited to areas where access and site activities enabled investigations to occur without unacceptable health and safety risks to personnel and/or unacceptable disruption to site operations. The sampling plan was discussed with site management prior to the commencement of works to assess this risk and was subject to alteration.

The main constraints on the implementation of the Stage 2 program were the presence of subsurface and overhead utilities and access restrictions within the buffer zone. Where these constraints were identified, the Decision Rules outlined in Step 5 of the DQO process (*Section 3.5.1*) were implemented

The proposed Stage 2 program included soil samples from 188 locations and groundwater samples from 133 locations. The completed Stage 2 program included soil samples from 173 locations and groundwater samples from 89 locations. An evaluation of the proposed and completed investigation locations for each AEC is provided in *Table 8 of Annex B* and on this basis it is considered that the number and distribution of completed boreholes and monitoring wells is sufficient for characterising soil and groundwater conditions for the purpose of this baseline assessment.

Deviations from the Stage 2 program were tracked during the course of the investigation via the weekly progress spreadsheet and were communicated to the relevant project stakeholders. An extract of the weekly progress spreadsheet is provided below as *Table 4.1* which highlights locations proposed but abandoned and the monitoring wells proposed but changed to soil bores during the course of the investigation.

**Table 4.1 Vales Point Power Station – Locations Abandoned or Changed to Soil Bores**

AEC	Location ID	Location Type	Change Details	Comments
VA	VA_MW07	Monitoring Well	Abandoned	Abandoned due to proximity of overhead and underground services. Surface is concrete hardstand.
VA	VA_MW08	Monitoring Well	Abandoned	
VA	VA_SB04	Soil Bore	Abandoned	
VB	VB_MW04	Monitoring Well	Abandoned	Abandoned due to proximity to critical services (stormwater and sewer which could not be identified using CAT GPR). Surface is concrete hardstand.
VB	VB_MW06	Monitoring Well	Abandoned	Locations are in an area containing deep stormwater drains and thick concrete rails used to move transformers. Not possible to drill in this location. Not possible to move location as area is confined by canal and former A station
VB	VB_MW07	Monitoring Well	Abandoned	Abandoned due to proximity to critical services (High Voltage Kiosk) that are not shown on plans. No safe location to move to.
VB	VB_SB02	Soil Bore	Abandoned	Abandoned due to the presence of multiple services in the area. No safe area to move location to.
VB	VB_SB04	Soil Bore	Abandoned	Locations are in an area containing deep stormwater drains and thick concrete rails used to move transformers in the area. Not possible to drill in this location. Not possible to move location as area is confined by canal and former A station
VC	VC_MW03	Monitoring Well	Changed to shallow soil bore	Shallow soil sample collected only due to the presence of multiple services in the area. No safe area to move location to.
VC	VC_SB02	Soil Bore	Abandoned	Abandoned due to proximity to stormwater pipes and anchor points for transformer rails. Concrete in this area likely to be 600 mm thick to support the weight of transformers
VE	VE_MW01	Monitoring Well	Changed to shallow soil bore	Shallow soil sample collected only, due to the presence of multiple services in the area. No safe area to move location to due to the presence of a slope on one side and services on 3 other sides.
VI	VI_MW03	Monitoring Well	Abandoned	Abandoned due to proximity of services, overhead cable trays and underground services.

COMMERCIAL IN CONFIDENCE

AEC	Location ID	Location Type	Change Details	Comments
VI	VI_SB01	Soil Bore	Changed to shallow soil bore	Changed to a shallow soil bore due to the presence of multiple services in a small area.
VI	VI_SB02	Soil Bore	Abandoned	Abandoned due to proximity of services, overhead cable trays and underground services.
VL	VL_SB01	Soil Bore	Changed to shallow soil bore	Changed to a shallow soil bore due to the proximity of main electrical services
VM	VM_MW02	Monitoring Well	Changed to shallow soil bore	Changed to a shallow soil bore as there is no safe location to advance a monitoring well. The location is in a 2m wide area between a canal and a building and contains multiple services.
VM	VM_MW05	Monitoring Well	Changed to shallow soil bore	Changed to a shallow soil bore due to the proximity of services, overhead cable trays and underground services.
VM	VM_SB01	Soil Bore	Changed to shallow soil bore	Changed to a shallow soil bore as there is no safe location to advance a monitoring well. The location contains multiple services.
VN	VN_MW04	Monitoring Well	Abandoned	Abandoned due to flooding in the area and therefore lack of access
VN	VN_MW11	Monitoring Well	Abandoned	
VO	VO_MW16	Monitoring Well	Changed to soil bore	Changed to soil bore due to the proximity to the Jemena gas pipeline
VT	VT_MW02	Monitoring Well	Abandoned	Abandoned as there is no safe location to drill due to topography and large truck turning circle.
VT	VT_MW03a	Monitoring Well	Changed to soil bore	Changed to a soil bore due to the location being within the turning circle of trucks.
VU	VU_MW11	Monitoring Well	Changed to shallow soil bore	Changed to a shallow soil bore due to bushy terrain and lack of access for drilling equipment.
VU	VU_MW18	Monitoring Well	Changed to soil bore	Changed to soil bore due to the proximity to the Jemena gas pipeline.
VU	VU_MW19	Monitoring Well	Abandoned	

Notes: extract from Weekly Progress Report

Final investigation locations are presented in *Figures 6.1 to 6.6 of Annex A*.

## 4.2 *SITE INSPECTION*

The work areas of the Site were inspected and the soil and groundwater sampling locations were marked out to target identified Site features and potential contamination sources. At the same time as clarifying the investigation locations, sub-surface utilities were marked out using an appropriately qualified service locator. Ground penetrating radar (GPR) and Cable Avoidance Tool (CAT), along with DBYD plans and Site engineering drawings were utilised to identify underground services and utilities.

## 4.3 *SOIL INVESTIGATION*

### 4.3.1 *Soil Sampling Procedure*

Soil investigation and sampling works were undertaken in general accordance with ERM's Standard Operating Procedures (SOPs). The location and number of sampling locations are presented within *Figures 6.1 to 6.6 of Annex A* and listed by AEC (Area VA – Area VU) in *Table 1 of Annex B*.

Where practicable, all boreholes were advanced to an initial depth of 1.5 m bgl using either hand augering or Non-Destructive Digging (NDD) techniques in accordance with ERM's sub-surface clearance procedures. Drilling and soil sampling of subsurface material beyond 1.5 m bgl, were undertaken using a Geoprobe® drilling rig with a continuous push tube sampler where conditions allowed. Other methods of borehole advancement included solid stem mechanical augering, and air rotary methods, where bedrock was encountered or subsurface material could not be penetrated using push tube methods.

Regardless of the drilling methodology adopted, soil sampling techniques which minimised the potential for loss of volatiles were utilised. Where the collection of undisturbed samples was not possible (e.g. during hand augering) the potential for loss of volatiles was minimised by sampling from larger clods and minimising the duration between sample excavation and placement into the sample container.

Field screening was conducted in accordance with ERM's SOPs using a photo-ionisation detector (PID) fitted with a 10.6 eV lamp, calibrated at the beginning of each working day. Calibration certificates are presented in *Annex E*. Where practicable, soil was collected at 0.5 m depth intervals (or where significant changes in lithology were identified) to 2 m bgl and at 1 m depth intervals thereafter. Soil samples were placed in a zip lock bag, sealed and screened for the presence of ionisable volatile compounds. Where the presence of volatiles or other impact was suspected, additional samples were collected.

Soil properties were logged by an appropriately trained and experienced field scientist in general accordance with *Australian Standard AS 1726-1993, Geotechnical Site Investigations* (Standards Association of Australia, 1993). Representative soil samples were collected for laboratory analysis at selected locations, based on visual and/or olfactory evidence of the following:

- multiple layers of fill material;
- changes in the soil profile; and
- potential impact.

Soil samples were collected, to the extent practicable, in accordance with techniques described in *Australian Standard AS4482-2005* (Parts 1 and 2) to maintain the representativeness and integrity of the samples. Soil samples for laboratory analysis were collected from either the hand auger or directly from the push tube core. No samples were collected for laboratory analysis from solid flight augers, unless otherwise stated within borehole logs presented in *Annex D*. The frequency and nature of field QA/QC samples collected during the assessment works are summarised in *Annex F*.

Soil samples were generally labelled using the nomenclature presented in *Table 4.2* (below).

**Table 4.2** *Sample Naming Protocol*

Sample	Identification
Sample taken from shallow hand auger soil bore or deeper soil bore, SB01 at depth of 0.5 m bgl, within work area VA	VA_SB01_0.5
Sample taken from depth of 5 m bgl from a soil bore to be installed as Monitoring Well MW07, within work area VA	VA_MW07_5.0
Sediment samples taken from SS01 within work area VM at a depth of 0.25 m below the surface of the sediment.	VM_SS01_0.25
Surface water samples taken from SW01 within work area VG	VG_SW01

Sample jars were sealed and immediately placed in an insulated cooler, on ice, and stored to reduce the potential for loss or degradation of volatile compounds. Samples were shipped under chain of custody documentation to the analytical laboratory. Trip blanks and field blanks were used to assess whether cross contamination occurred during the sample collection process.

No potential asbestos containing material (ACM) was identified at the surface or during the investigation works, and there were no ACM fragments submitted for analysis. Discrete 500 mL samples of soil were collected in snap lock bags during NDD for laboratory analysis for asbestos fibres. These samples were submitted to the laboratory for asbestos identification and (where identified) quantification (%w/w analysis) in accordance with the WA DOH guidelines (WA DOH, 2009).

#### 4.3.2 *Decontamination Procedure*

Down-hole drilling and non-single use sampling equipment was decontaminated by initially removing any residual soil with a stiff brush and then washing the equipment in a 2% Decon 90 solution and rinsing with potable water.

#### 4.3.3 *Soil Bore Reinstatement*

Upon completion, soil bores were backfilled and the surface covering reinstated to match existing.

#### 4.3.4 *Management of Waste Materials Generated During Drilling*

Non-liquid waste materials generated during drilling works were stored on-site in stockpiles inside a temporary bund in a designated area near the Vales Point Power Station Ash Dam, prior to disposal within the Ash Dam in accordance with environmental licence conditions.

### 4.4 *GROUNDWATER INVESTIGATION*

#### 4.4.1 *Monitoring Well Construction*

Selected boreholes were converted to groundwater monitoring wells in accordance with ERMs SOPs. The groundwater monitoring well locations are presented in *Figures 6.1 to 6.6 of Annex A*. The following methodology was implemented to install new monitoring wells:

- wells were constructed of heavy duty 50 mm diameter class 18 uPVC with factory slotted screen (0.4 mm slots) and plain well casing. Where practicable, the wells were screened within groundwater bearing strata in accordance with ERMs SOPs with consideration of potential regional and seasonal fluctuations of the water table and constructed to allow the potential ingress of Non-Aqueous Phase Liquids (NAPL);
- following drilling, the well casing and screen were inserted into the drill casing. Washed and graded filter sand was poured into the annulus between the well screen and casing wall, ensuring that the sand covered the entire screened level and extended approximately 0.5 m above the top of the well screen;
- bentonite granules were then poured on top of the sand to an approximate thickness of 1 m and hydrated to effectively seal off the well from surface water or perched/shallow groundwater inflows; and

- the remaining annulus from the top of the seal to the base of the concrete was grouted with cement/bentonite grout to within 0.25 m of the surface and the final 0.25 m reinstated with concrete and a heavy duty well cover (flush gatic cover or raised monument as appropriate). The well casings were sealed with air-tight, lockable 'Envirocaps'.

Following monitoring well installation, each well was developed using a submersible 12V electric 'Typhoon' pump to remove any fine or granular materials or contaminants potentially introduced during drilling and to optimise hydraulic connectivity with the surrounding aquifer. Wells were considered developed when either a minimum of 10 well volumes had been removed, when water quality parameters had stabilised or if the well was developed dry prior to this.

Monitoring well construction details are presented within the borehole logs in *Annex D*.

#### 4.4.2 *Groundwater Purging and Sampling Protocol*

Groundwater purging and the sampling of newly installed monitoring wells generally occurred at least one week following monitoring well installation and development, to allow subsurface conditions to stabilise. Both new and existing monitoring wells were purged and sampled as outlined below.

The presence of odours was noted, where applicable, following removal of the well cap and prior to purging. Any odours were described by reference to their intensity and character.

Following a period of no pumping (as a minimum 24 hours), wells were dipped to gauge the depth to groundwater, and the potential presence and depths of NAPLs.

Monitoring wells were purged using either a thoroughly decontaminated peristaltic or micro purge pump under low flow conditions, where hydrogeological conditions allowed, until sufficient water has been removed to obtain stabilised measurements of pH, conductivity, oxidation-reduction potential (ORP), temperature and dissolved oxygen which was calibrated prior to use. The stabilisation criteria are as described below.

**Table 4.3** *Water quality parameter stabilisation criteria*

<b>Parameter</b>	<b>Stabilisation criteria</b>
pH	± 0.1 pH units
Electric Conductivity (EC)	± 3% (µS/cm or mS/cm)
Temperature	± 0.5°C
Oxidation Reduction Potential (ORP)	± 10 mV
Dissolved Oxygen (DO)	± 0.3 mg/L

It is noted that both ORP and DO are typically slower to stabilise than the other parameters. Where ORP and DO did not stabilise, therefore, greater weight was given to pH and EC as the stabilising parameters.

Low-flow sampling techniques were used to obtain samples that were representative of the local groundwater environment at the Site. The inlet of the low-flow purge pump was placed approximately 50 cm from the base of the well in order to obtain a representative sample. Water samples were collected using equipment dedicated to each monitoring well to reduce the potential for cross-contamination between sampling locations.

The following order of sampling was adopted:

- samples to be analysed for volatile compounds placed into 40 mL amber vials;
- samples to be analysed for semi-volatile compounds placed into one 100 mL solvent washed amber bottles and one, 1 litre solvent washed amber bottle (for inter-laboratory duplicate samples);
- samples to be analysed for dissolved metals filtered through disposable 0.45 µm filters and placed in 60 mL plastic bottles preserved with nitric acid, or 60 mL unpreserved plastic bottles for ultra-trace metals;
- samples to be analysed for ferrous iron filtered through disposable 0.45 µm filters and placed in 60 mL plastic bottles preserved with hydrochloric acid; and
- samples to be analysed for major cations and anions placed in an unpreserved 250 mL plastic bottle.

Light Non-Aqueous Phase Liquid (LNAPL) was not observed at any of the sampling locations or detected with an interface probe.

The containers were filled, where practical, to minimise headspace, before being sealed and appropriately labelled. Labels included the following information:

- sample identification number;
- sampler;
- job number; and
- date of collection.

Samples were sealed and immediately placed in a cooler on ice to minimise potential for degradation of the sample. All samples were shipped under chain of custody documentation to the analytical laboratories.

#### 4.4.3 *Waste Material Generated During Groundwater Development/Purging*

With approval from Delta Electricity, waste water from development and purging of groundwater monitoring wells was disposed of into the Ash Dam.

#### 4.5 *SURVEYING*

All soil bore investigation locations were digitally located by field staff with a handheld Global Positioning System (GPS) unit. Additionally, all groundwater monitoring wells were surveyed by a registered surveyor (Monteith and Powys) to AHD for elevation and MGA coordinates for location. Survey data is presented in *Annex J*. The elevation of the highest point of the top of the uPVC well casing was surveyed to facilitate appropriate groundwater elevation calculations and groundwater flow direction interpretations.

#### 4.6 *SEDIMENT INVESTIGATION*

Sediment samples were collected from within Wyee Bay, Chain Valley Bay, Wyee Creek and the Wyee Creek diversion channel, and Mannering Bay.

Sediment samples were collected in general accordance with the methodologies outlined in *CSIRO Handbook for Sediment Quality Assessment* (2005). Sediment was collected from each sampling location with either a stainless steel van Veen grab sampler or a polycarbonate push tube.

The grab sample was inspected and if it was deemed to be of acceptable quality i.e. van Veen fully closed, the sediment-water interface undisturbed with no evidence of loss of fines, and sufficient sample volume, the sediment was transferred to a container and homogenised.

The samples collected using polycarbonate push tubes were laid out within a one metre core catcher and split into multiple depths for sampling.

If there was insufficient sample volume in a single grab or core sample, but the sample was otherwise of acceptable quality, sediment from multiple grabs/cores was included in the sample.

Sample handling and labelling procedures were consistent with those adopted for soil sampling and those outlined in *Handbook for Sediment Quality Assessment* (CSIRO, 2005). The sediment volume, colour, grain size, odour, and presence of debris, organic matter, or biota were noted. Sediment samples were transferred to laboratory supplied glass jars for chemical analysis and 500 mL 'snaplock' bags for grain size analysis. Care was taken to minimise head space in the sample jars to reduce the potential for loss of volatile COPCs. The samples were stored on ice and transported under chain of custody to the analytical laboratory.

The van Veen, core and all other equipment used in the process of collecting the sediment samples were decontaminated (using the same procedures as those previously outlined for soil sampling equipment) between sampling locations.

#### 4.7 *SURFACE WATER INVESTIGATION*

Surface water samples were collected from Lake Macquarie and Wye Creek. Surface water samples were collected approximately 1 m from the bottom using a van Dorn sampler. If there were any locations where water depth was not sufficient for van Dorn deployment, samples were collected by hand, holding the sampling container beneath the surface of the water with the container facing upstream, while avoiding disturbing substrate.

Sample containers were sealed and immediately placed in a cooler on ice to reduce the potential for degradation of organic compounds. The samples were transported under chain of custody documentation to a NATA accredited laboratory at the end of each day.

A calibrated water quality meter was used to measure field parameters including pH, conductivity, oxidation reduction potential, temperature, total dissolved solids (TDS), and dissolved oxygen. Observations of the general condition of the surface water and its surrounds were recorded during sampling.

#### 4.8 *LABORATORY ANALYSIS*

The laboratories used for the investigations were accredited by the National Association of Testing Authorities (NATA), Australia. The primary laboratory used for soil and groundwater analysis was ALS Environmental Pty Ltd (ALS). Inter-laboratory duplicate samples were analysed by a secondary laboratory, Envirolab Services Pty Ltd (Envirolab). The analytical methods used by each laboratory are provided in the laboratory certificates in *Annex H*.

Soil, sediment, groundwater and surface water samples were analysed for the following COPCs:

- metals and metalloids (arsenic, cadmium, chromium, copper, nickel, lead, mercury, selenium and zinc);
- Total Recoverable Hydrocarbons (TRH); and
- Polycyclic Aromatic Hydrocarbons (PAHs).

Additional contaminants of concern were analysed within individual AECs to target specific sources of contamination or if required based on observations made in the field.

These contaminants include:

- Polychlorinated Biphenyls (PCBs) - related to use of PCB-containing transformer oil on site;
- Volatile Organic Compounds (including benzene, toluene, ethylbenzene and xylenes - BTEX); and
- Perfluorooctane sulfonate (PFOS) and Perfluorooctanoic acid (PFOA) - to target areas where fire retardants may have been used or stored;
- Asbestos (soil only).

Selected soil samples were also analysed for the following to allow for adoption of appropriate screening values:

- Total Organic Carbon (TOC);
- Particle Size Distribution (PSD);
- Electrical Conductivity (EC); and
- pH and Cation Exchange Capacity (CEC).

#### 4.9 *QUALITY ASSURANCE/QUALITY CONTROL*

A detailed QA/QC report including field procedures, laboratory methods and an analysis of QA/QC results from the investigation is provided in *Annex F*. QA/QC information incorporating inter-laboratory and intra-laboratory duplicates, rinsate samples and trip spike/blank samples are also tabulated in *Annex F*.

In summary, the QA/QC data reported by ALS for soil and groundwater samples and field duplicate results were generally free of systematic and method biases and were assessed to be of sufficient quality for the purposes of this investigation.

There were some instances where the adopted screening values were less than the laboratory LOR. These potential non-conformances are discussed in *Section 5.5* of this report.

#### 4.10 *DATA SCREENING*

Individual soil, groundwater, sediment and surface water data, along with the maximum, minimum, mean, standard deviation and 95% upper confidence limit (UCL) of the mean concentration (if required) were compared to adopted screening values.

The screening values adopted for the Site are designed to provide a screening value assessment of potential risks that may be associated with the SPR linkages that have been identified for this Site. The specific assessment levels adopted are presented alongside the analytical data in the summary tables presented in *Annex B*. The approach to the screening of the data gathered in this assessment has generally been to initially adopt conservative assessment values. Any exceedances of these values have then been evaluated on a case by case basis, in light of the specific characteristics of the individual sample and the area of the Site from which the sample was collected.

The adopted screening values have generally been sourced from guidelines made or approved under the *CLM Act 1997*, which includes the *ASC NEPM (ASC NEPC, 2013)*. Where alternative sources have been utilised, appropriate justification has been provided.

#### 4.10.1 *Soil Screening Values*

Soil data was assessed against investigation criteria published in the NEPC (2013) *National Environment Protection (Assessment of Site Contamination) Measure 1999*, Schedule B1 - Guideline on Investigation Levels for Soil and Groundwater (ASC NEPC, 2013), including;

- Health Investigation Level (HIL) - 'D' Commercial/Industrial
- Health Screening values (HSLs) for Vapour Intrusion and Direct Soil - 'D' Commercial/Industrial
- Ecological Investigation / Screening values (EILs/ESLs) - for areas of ecological significance and commercial industrial areas (as applicable).
- The Cooperative Research Centre for Contamination Assessment and Remediation of the Environment (CRC CARE, 2011) *Technical Report No. 10* HSLs for Vapour Intrusion and Direct Contact - Intrusive Maintenance Workers (labouring within shallow trenches).

The EILs/ESLs for commercial/industrial areas have been adopted across the Site and the EILs/ESLs have been adopted only in areas where threatened and/or endangered species have been identified (i.e. AECs including the Ash Dam, Wyee Rail Coal Unloader area and Site Buffers and Boundaries).

Laboratory analysis for pH and CEC is required to establish site specific EILs/ESLs, and an assessment of background conditions is necessary. The establishment of EILs/ESLs was undertaken, and sample locations in buffer/boundary locations were utilised in establishing background conditions. The details of the calculations used to establish Site specific EILs/ESLs are provided in *Annex I*.

The ASC NEPM (2013) also provides EILs for aged and fresh contamination for the metal constituents Ni, Cr III, Cu, Zn and Pb. For the purposes of EIL derivation, a constituent incorporated in soil for at least two years was considered to be aged. Given that the Site has been operational since the 1960s and no significant individual release events of these metals have been recorded, any identified impacts are likely to primarily represent aged contamination. The EILs for aged contamination have been adopted.

The ASC NEPM (2013) and CRC CARE (2011) *Health screening values for petroleum hydrocarbons in soil and groundwater* provide Health Screening values (HSLs) for soil and groundwater impacts located at depths from 0 to 4+ m bgl in soil types ranging from sand to clay and Health Investigation Levels (HILs) for shallow soil impacts. The screening values for sandy soils have been adopted across the Site, as a conservative approach. The significance of any exceedances of the HILs/HSLs have been evaluated on a case by case basis, with reference to the use of the area of identified potential concern.

#### 4.10.2 *Groundwater and Surface Water Screening Values*

Water data has been assessed against investigation criteria published in NEPC (NEPC, 2013) *National Environment Protection (Assessment of Site Contamination) Amendment Measure 2013 (No. 1)*, Schedule B1 - Guideline on Investigation Levels for Soil and Groundwater including;

- Australia and New Zealand Environment and Conservation Council and Agriculture and Resource Management Council of Australia and New Zealand (ANZECC and ARMCANZ, 2000) *Australian and New Zealand Guidelines for Fresh and Marine Water Quality* - Trigger values for marine water, level of protection 95% species;
- National Health and Medical Research Council and National Resource Management Ministerial Council (NHMRC and NRMCMC, 2013) *Australian Drinking Water Guidelines Paper 6 National Water Quality Management Strategy*;
- National Health and Medical Research Council (NHMRC, 2008) *Guidelines for Managing Risks in Recreational Waters* - note that these will be applied with reference to (ANZECC/ARMCANZ, 2000) and (NHMRC and NRMCMC, 2013) referenced above; and
- Cooperative Research Centre for Contamination Assessment and Remediation of the Environment (CRC CARE, 2011) *Technical Report No. 10, Health Screening values for Petroleum Hydrocarbons in Soil and Groundwater*. HSLs for Vapour Intrusion - 'D' Commercial and Intrusive Maintenance Worker (Shallow Trench).

The groundwater beneath the Site is not considered to be an ecological receptor of concern in itself, but the trigger values for the protection of 95% of marine species have been adopted across the Site to evaluate potential risks associated with the discharge of groundwater into the marine environment of Lake Macquarie.

Groundwater is not extracted for potable use across the Site. The National Health and Medical Research Council (NHMRC) (2011) *Australian Drinking Water Guidelines*, however been adopted across the Site to evaluate the requirement to report groundwater contamination across the Site, in accordance with the DECC (2009) *Guidelines on the Duty to Report Contamination under the Contaminated Land Management Act 1997*. The potable use of groundwater has been considered for areas in proximity to residential areas - namely AEC VO (Ash Dam) and VU (Site Buffers and Boundaries).

#### 4.10.3 *Sediment Screening Values*

Sediment quality data have been assessed against screening values published in:

- (ANZECC and ARMCANZ, 2000) *Australian and New Zealand Guidelines for Fresh and Marine Water Quality - Interim Sediment Quality Guidelines (ISQGs)*, or the equivalent Commonwealth of Australia (DEWHA, 2009) *National Assessment Guidelines for Dredging*. (ANZECC/ARMCANZ, 2000).

Where no Australian endorsed assessment levels are available reference has been made to the following National Institute of Public Health and the Environment (RIVM) document:

- (RIVM, 2001) *Ecotoxicological serious risk concentrations for soil, sediment and (ground)water - updated proposals for first series of compounds*.

It is noted that these guideline values have no regulatory standing in NSW and hence these values have been adopted to provide a high level evaluation of potential ecological risk and have not been used to assess the duty to report requirements under the Contaminated Land Management (CLM) Act 1997.

#### 4.10.4 *Screening values for Perfluorooctane Sulfonate (PFOS) And Perfluorooctanoic Acid (PFOA)*

##### *Soil*

No authoritative screening criteria have been published within Australia for assessing chronic risks to human health from either perfluorooctane sulfonate (PFOS) or Perfluorooctanoic acid (PFOA) in soils. As such, a literature review and web-based research were conducted to identify conservative screening values for these COPCs.

Values of 6 mg/kg and 16 mg/kg were adopted for PFOS and PFOA in soil respectively, based on recently published US EPA Region 4 guidance *Emerging Contaminants Fact Sheet –PFOS and PFOA, May 2012* (US EPA, 2009c) for residential land-use settings. Whilst these criteria are acknowledged to be designed for application to a more sensitive land-use, they are considered appropriate to inform requirements for more detailed, or site-specific, risk characterisation.

It is noted that these guideline values have no regulatory standing in NSW and hence these values have been adopted to provide a high level evaluation of potential ecological risk and have not been used to assess the duty to report requirements under the CLM Act (1997).

#### *Groundwater*

No authoritative guidelines have been published in Australia for PFOS or PFOA in groundwater, protective of human health or the environment.

Whilst groundwater is not used on-site for potable supply, in the absence of a more appropriate guideline, a health screening values of 0.2 and 0.4 µg/L for PFOS and PFOA respectively in groundwater have been adopted. These values are proposed by the US EPA (2009).

Whilst groundwater beneath the Site is not considered to be an ecological receptor in itself, ecological impacts may be associated with the discharge of groundwater into the adjacent marine environment of Wyee Creek and Lake Macquarie. In the absence of a local guideline, an ecological screening value of 7.2 µg/L has been adopted for PFOS. This value was recommended by (RIVM, 2010) as the Maximum Acceptable Concentration (MAC) for marine ecosystems.

It is noted that these guideline values have no regulatory standing in NSW and hence these values have been adopted to provide a high level evaluation of potential ecological risk and have not been used to assess the duty to report requirements under the CLM Act (1997).

#### **4.10.5** *Screening Values For Selenium*

ANZECC and ARMCANZ (2000) provides a low reliability marine trigger value for selenium, which has been adopted as the ecological screening value for surface water and groundwater in this assessment.

In the absence of ANZECC and ARMCANZ (2000) screening values for selenium in sediment, the British Columbia Ministry of Environment (2001) *Ambient Water Quality Guideline* marine sediment screening value for selenium of 2 mg/kg has been adopted in this assessment. This value is designed to be protective of selenium bioaccumulation through the food chain and direct selenium toxicity.

It is noted that these guideline values are not regulatory criteria in British Columbia and have no regulatory standing in NSW and hence these values have been adopted to provide a high level evaluation of potential ecological risk and have not been used to assess the duty to report requirements under the CLM Act (1997).

5 **RESULTS AND DISCUSSION**

5.1 **SITE GEOLOGY OBSERVATIONS**

A generalised description of the lithology and geology encountered at the Site is presented in Table 5.1.

Alluvial sediments, ranging from clayey sand to clay in texture with sandy clay predominating in the majority of bore locations, were encountered at relatively shallow depths in some sections of the Site, generally in close proximity to Mannering Creek, Mannering Bay and Lake Macquarie. Highly weathered conglomerate with minor sandstone and siltstone of the Munmorah Conglomerate formation was encountered across the majority of the Site. The highly weathered nature of the Munmorah Conglomerate is attested by the fact that the majority of monitoring well bores were able to be drilled with solid flight augers or hollow stem augers following refusal with push-tube methods.

Moderately weathered to unweathered rock was encountered in ten locations (including VA\_MW03, VA\_MW06, VL\_MW02, VN\_MW03, VN\_MW10, VO\_MW08, VU\_MW08, VU\_MW09, VU\_MW13 and VU\_MW14) within the Munmorah Conglomerate. These bores were generally completed using the rotary air percussion method. Depths to the unweathered conglomerate in these locations generally varied from 5 to 6 m bgl, and the unweathered sedimentary rock extended to 15 m bgl (the maximum depth of the investigation). Dykes identified on the geology map for the area (see Section 2.2.3) were not encountered during the drilling program.

**Table 5.1 Generalised Field Lithology Descriptions**

<b>Lithological Unit</b>	<b>Description</b>	<b>Depth<sup>1</sup> (m bgl)</b>
Hardstanding	Concrete and asphalt generally in good condition (present in some locations within the operational area).	0 - up to 0.35
Fill	Fill material of variable composition, varying from sandy gravel to gravelly sandy clay (present in some locations within the operational area).	0 - up to 2.8
Alluvial Sediments	Generally poorly sorted sediments, ranging from clayey sand to clay with sandy clay predominating in the majority of bore locations.	0 - up to 6
Munmorah Conglomerate	Highly weathered conglomerate with minor sandstone, siltstone and mudstone. The conglomerate contained a heterogeneous gravel lithology, with matrix (>15%) generally consisting of silty sand. The Munmorah Conglomerate underlies the majority of the site. Relatively unweathered rock was encountered at depths varying from 7.5 to 15 m bgl.	Highly weathered: 0 - up to 13.  Moderately weathered to unweathered: 3.4 - ≥15
1. Given the variation in topography across the Site, depths and lithologies may vary across the site.		

Detailed descriptions of the Site lithology and geology as observed at each location during the investigation are presented in the borehole logs in *Annex D*.

## 5.2 GROUNDWATER FIELD OBSERVATIONS

Newly installed monitoring wells were generally gauged and sampled at least 72 hours after well installation and development to allow subsurface conditions to stabilise. Groundwater gauging and sampling was completed for newly installed and existing monitoring wells between 20 March and 1 April 2014.

Groundwater gauging data is presented in *Table 2 of Annex B*. Groundwater was encountered at depths ranging from the near surface (001 m bgl in VO\_MW12) to 9.80 m bgl, or -0.13 m AHD to 38.67 m AHD in the alluvial sediments and the highly weathered Munmorah Conglomerate. Potentiometric water levels in the moderately weather to unweathered sedimentary rock, where groundwater storage and flow is expected to be governed mainly by fractures within the rock matrix, varied from 1.24 bgl to 9.73 m bgl, or 0.57 m AHD to 27.02 m AHD. For monitoring wells drilled into fractured rock, stabilised water levels were well above water strikes where observed as well as above the interface between the highly weathered and less weathered conglomerate, and the groundwater levels in these monitoring wells are considered to present potentiometric water levels.

The interpolated groundwater contouring indicates that groundwater flow in the alluvial sediments and highly weathered Munmorah Conglomerate is generally in a northerly direction towards Lake Macquarie for the majority of the site (see *Figure 7*) and to the east north-east from the Wyee rail coal unloader area. Localised variations in groundwater flow direction occur at the ash dam as governed by local variations in topography, with the groundwater gauging indicating a westerly groundwater flow component downgradient of the south-western most section of the ash dam, towards the east downgradient of the south-easterly section of the ash dam and toward the north and Mannering Bay downgradient of the north-western section of the ash dam. Groundwater contours for the monitoring wells intersecting the deeper lying fractured conglomerate have not been interpolated as the number and spread of monitoring wells in the deeper lying fractured rock do not facilitate the interpolation of groundwater contours. Groundwater flow in this unit is however expected to be towards Lake Macquarie, located to the north for the majority of the Site and to the east north-east for the Wyee rail coal unloader area.

Field records for groundwater well development and sampling are presented in *Annex E*. Groundwater field parameters recorded during purging of wells prior to sampling are presented in *Table 3 of Annex B*.

An additional round of groundwater sampling was undertaken on 27 May, 2014. Specific wells were sampled in order to delineate previously identified impacts, and to provide further data, specifically:

- Additional sampling of VP\_MW01 where Benzene was detected a concentration greater than the adopted drinking water screening levels, to assess temporal variation.
- Sampling of VB\_MW03. Due to a communication error, samples from this well had not previously been analysed.
- Sampling of surface water near the 'toe drain' area of the Ash Dam to provide further data on metals concentrations in this area.

### 5.3 *AREAS OF ENVIRONMENTAL CONCERN (AEC) SUMMARY*

This section discusses the analytical results of the soil, sediment, surface water and groundwater samples collected in each of the Areas of Environmental Concern (AEC's). It is noted that metals have been identified at concentrations exceeding the adopted screening criteria in groundwater within all AECs and that background conditions contribute to these impacts in some areas of the site. As such, groundwater metal data has not been discussed in the context of each individual AEC; a consolidated discussion of this issue is presented in *Section 5.4*.

#### 5.3.1 *VA - B Station Power Block*

##### *Background*

The main generating plant area of the Vales Point Power Station operates two 660 MW generating units (B Station) and associated infrastructure including;

- coal feed systems;
- two coal-fired boilers;
- turbine house incorporating two steam turbines;
- two 660 MW generator units (units 5 and 6);
- emergency diesel generator; and
- one chimney stack (serving two boilers).

Electricity is produced using pulverised coal-fired boilers. The coal is ground in pulverising mills before being blown into the boiler in a stream of pre-heated air. The coal burned in the boiler furnace chamber produces the heat necessary to convert water circulating in the boiler tubes into high-pressure steam.

The electricity generation process involves high pressure steam passing through cylinders and spinning the shaft of each generator and inducing alternating current. After use, the steam is condensed back to water and is recycled.

The primary source of potential contamination identified in this area is potential leaks of lubricating oil and diesel fuel at various points around the plant. Observations during the Site visit confirmed this oil loss in various areas. In particular during the Phase 1 investigation, surface staining and/or oily surface water was noted in the area of the emergency generator diesel tank and oil unloading area for the turbine oil storage tanks.

A major fire event also occurred in the 5A Air Heater in November 2011. Although there is no information to suggest that Aqueous Film Forming Foam (AFFF) was used for firefighting, in conjunction with this event, PFOS and/or PFOA have been included as COPC for this area.

Within the power block, leaks and spills are generally captured in internal contaminated water drains and transferred to the oil and grit separator and Chain Valley Retention Basin, located in the north eastern corner of the site. However, there remains potential for seepage of leaks and spills through cracks in the concrete around infrastructure.

Various small workshops are present throughout the power block which service specific areas. Many of these workshops hold small quantities of lubricating oils, solvents and similar chemicals. During the Site works dangerous goods were generally observed to be appropriately stored within bunded or contained areas. However, staining of the concrete surface in various areas of the workshops was observed, and there remains potential for spills and leaks to penetrate the concrete through cracks and joints into the subsurface.

The network of drains which runs beneath the power block also represent a potential contamination source to soil and groundwater due to the subsurface nature of this network and the various COPCs (including corrosive chemicals) likely to be currently present or having been historically present as a result of the collection and conveyance of spills and leaks in various areas. In addition to the dedicated stormwater and contaminated water drainage systems, a sluiceway which transports ash and coal fines collected in various surface drains in the power block runs through the power block, eventually discharging into the Ash Dam.

No soil or groundwater investigations are known to have been undertaken to date which specifically target the B Station Power Block. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

*AEC Methodology and Investigation Field Observations*

A total of nine soil investigation bores, six of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater. Due to the potential health and safety risks from the operational nature of this area investigation locations were distributed around the perimeter of the AEC to identify COPC that may have migrated from within this AEC.

Sampling locations were distributed around the AEC as presented in *Figure 6.3 of Annex A*. Relevant borehole logs are presented within *Annex D*.

Monitoring wells VA\_MW07 and VA\_MW08, located in the north west corner of the investigation area, were abandoned due to the proximity to both overhead and underground utilities. Soil bore VA\_SB40 was also abandoned due to the proximity of overhead and underground utilities. However, the position of monitoring well VC\_MW01 in the adjacent transformer area (AEC VC) provides sufficient interception of potential off-site migration of COPCs from the north west corner of the B Station Power Block AEC.

Black staining and an unknown odour were observed at VA\_SB01 at a depth of 0.2 to 0.3 m bgl. There were no other field indicators of contamination, such as staining or odours detected at any depth during the sampling process within this AEC. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 8 parts per million by volume (ppm v) (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.2*.

**Table 5.2** *Field Observations Summary – AEC VA*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v -isobutylene equivalents)
VA_MW01	3	None	0-0
VA_MW02	14	None	0-8.0
VA_MW03	12	None	0-3.4
VA_MW05	7.5	None	0-0.2
VA_MW06	11.5	None	0-1.6
VA_SB01	0.95	Black staining and odour at 0.2- 0.3 m bgl	0-1.0
VA_SB02	1.05	None	0
VA_SB03	3.0	None	0-1.6

Groundwater samples were collected from six groundwater monitoring wells within the B Station Power Block AEC. Groundwater parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*. Electrical conductivity measurements were generally indicative of freshwater conditions, with a range between 583-714  $\mu\text{S}/\text{cm}$ , with the exception of two monitoring wells, VA\_MW01 (2168  $\mu\text{S}/\text{cm}$ ) and VA\_MW05 (1417  $\mu\text{S}/\text{cm}$ ) which were indicative of brackish groundwater conditions. pH measurements were typically neutral to slightly acidic (pH 5.98 to 6.78) with the exception of acidic conditions indicated in VA\_MW05 (pH 4.44) located on the northern boundary.

No indications of contamination such as sheens or odours were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3 of Annex B*.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4a of Annex B*

Measured concentrations of COPCs were below the adopted human health screening values in all soil samples collected from within this AEC with the exception of carcinogenic PAHs at VA\_SB01 at a depth of 0.25 m bgl. Concentrations of TRH were also reported above the laboratory LOR in this sample however did not exceed the adopted human health screening values. Measured concentrations of PFOS were detected above the laboratory LOR in two soil samples at VA\_MW05 at a depth of 0.1 m bgl and VA\_MW02 at a depth of 0.1 m bgl, however the measured concentrations of PFOS did not exceed the adopted screening value.

Measured concentrations of COPCs were below the adopted ecological screening values in all soil samples collected from within this AEC with the exception of zinc at VA\_MW02 at a depth of 0.1 m bgl, nickel at VA\_MW02 at a depth of 2 m bgl and benzo(a)pyrene at VA\_SB01 at a depth of 0.25 m bgl.

The majority of the remaining measured concentrations were below the corresponding laboratory LOR with the exception of various heavy metals, however all of these concentrations were below the adopted screening values.

#### *Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5a of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of the majority of the COPCs were below the laboratory LOR in all groundwater samples analysed. The exceptions to this were some detections of metals within groundwater across this AEC.

It is noted that PFOS/PFOA were not detected in groundwater beneath this AEC. These chemicals would have been expected if the extensive use of AFFF had occurred in this area.

#### *Discussion*

One exceedance of the adopted human health screening values was identified in a soil sample collected from VA\_SB01, with no further exceedances identified in soil samples collected from within this AEC.

The shallow fill material at VA\_SB01 at a depth of approximately 0.2 to 0.3 m bgl was observed to be heterogeneous gravelly sandy clay with black staining and an unknown odour.

The corresponding laboratory results for VA\_SB01 at a depth of 0.25 m bgl exceeded the human health screening value for carcinogenic PAHs, and exceed the ecological screening value for benzo(a)pyrene. Based on the laboratory results, it is likely that the odour observed was related to the presence of hydrocarbons in soil at this depth. The PAH impacts in soil at this location appear to be localised and limited to the shallow soil, as vertically delineated by laboratory results from VA\_SB01\_0.8. It is noted that the soil bore VA\_SB01 was abandoned at a depth of 0.9 m bgl at refusal on conglomerate, and that water was observed to be infiltrating at the base of the bore.

As discussed in Schedule B7 of the ASC NEPM (2013), benzo(a)pyrene (and other carcinogenic PAHS) are not considered sufficiently volatile to be of significance and inhalation exposures associated with particulates outdoors and indoors are expected to be of less significance than ingestion of soil. The majority of this AEC is covered in hardstanding, including the area in the proximity of the soil bore VA\_SB01, and therefore the exposure to this chemical could only occur through direct contact with the soil or exposure to dust. The measured concentration of PAH constituents in groundwater in all monitoring wells within this AEC were below the laboratory LOR and the adopted screening values. Therefore, it is considered that the detected concentrations of PAH constituents in soil at VA\_SB01 are not contributing to impacts in groundwater. On this basis, the PAH impacts identified in this location are considered unlikely to represent a significant risk to human health or the environment under the ongoing operational use of the Site.

Zinc and nickel concentrations marginally exceeded the adopted ecological screening values in shallow soil sampled from VA\_MW02 at a depth of 0.1 m bgl and 2 m bgl, respectively. These exceedances are likely attributed to the composition of fill materials placed in this area. It is noted that the B Station Power Block AEC is an operational area and is primarily covered in hardstanding. These impacts are therefore considered unlikely to represent a significant risk to the terrestrial environment assuming ongoing commercial industrial use in the current or similar configuration.

### 5.3.2

#### *VB - Former A Station*

##### *Background*

Vales Point A Station was built in the 1960s as a four-unit station. These generating units were decommissioned in 1989 and since then have undergone partial dismantling, with most of the internal plant items removed. During ERMs Site works the A Station buildings were undergoing demolition and removal offsite.

Prior to the decommissioning and demolition of A Station, this facility was comprised of;

- four coal-fired boilers;
- a turbine house incorporating four steam turbines;
- four generator units (units 1 to 4), with a total capacity of 875 MW;
- an auxiliary bay; and
- two chimney stacks (serving four boilers).

ERM understands that once the demolition is complete, the A Station basement level concrete will remain and in other areas the ground surface will be covered with recycled crushed concrete and left vacant.

The primary sources of potential contamination within the former A Station area are associated with historic lubricating oil and fuel leaks at various points around the plant and leaks from the oily water drainage network.

Intrusive investigations have not previously been completed within the former A Station. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area. Due to the high probability of encountering unmarked subsurface utilities historically associated with the operation of the facility, the investigation locations targeting this AEC have therefore been focused around the perimeter of the AEC to identify COPC that may have migrated from this AEC.

*AEC Methodology and Investigation Field Observations*

A total of five soil investigation bores, four of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater.

The sampling locations advanced within this AEC are presented on *Figure 6.5* of *Annex A*. Relevant borehole logs are presented within *Annex D*.

During the sampling process, no field indicators of contamination, such as staining or odours were detected within this AEC. No staining or unusual odours were detected at any depth through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis of 13.3 and 23.5 ppm v (isobutylene equivalent) at VB\_MW03 at a depth of 3.8 to 4.0 m bgl were not associated with visual or olfactory evidence of contamination. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 23.5 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.3*.

**Table 5.3** *Field Observations Summary - AEC VB*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v - isobutylene equivalents)
VB_MW01	4	None	0
VB_MW02	4	None	0-1.5
VB_MW03	5.1	None	0-23.5
VB_MW05	6	None	0-1.0
VB_SB01	0.95	None	0-1.0

Groundwater samples were collected from four groundwater monitoring wells within the former A Station AEC. Groundwater parameter measurements collected during the groundwater sampling works are presented in *Table 3* of *Annex B*. Electrical conductivity (EC) measurements ranged from 570-2006 µS/cm, which indicates fresh to slightly brackish groundwater conditions. pH measurements were slightly acidic at VB\_MW02 and VB\_MW05 (pH of 5.77 and 5.5, respectively) and acidic at VB\_MW01 and VB\_MW03 (pH of 3.92 and 4.28 respectively). The acidic pH at VB\_MW01 and VB\_MW03 may indicate the presence of acid sulfate soil conditions within the western part of this AEC.

No indications of contamination such as sheens or odours were observed during groundwater sampling within this AEC, however a slight sulfurous odour was detected during the gauging in VB\_MW03. A summary of field observations from the groundwater sampling works are presented within *Table 3* of *Annex B*.

*Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.b of Annex B*.

Concentrations of TRH and PAHs were reported above the laboratory LOR in soil samples at VB\_MW01 at a depth of 0.5 m bgl and VB\_MW02 at a depth of 0.5 m bgl; however all concentrations were below the adopted human health screening values. Concentrations of PFOS were reported above the laboratory LOR in the soil sample collected from VB\_SB01 at 0.5 m bgl however the detected concentration was below the adopted screening value.

Measured concentrations of COPCs were below the adopted ecological screening values in the soil samples collected from within this AEC with the exception of TRH C<sub>10</sub>-C<sub>16</sub> (excluding naphthalene) in the soil sample collected from VB\_MW01 at a depth of 0.5 m bgl.

The majority of remaining measured concentrations of COPCs in soil samples analysed were below the corresponding laboratory LOR with the exception of various heavy metals, however all of these concentrations were below the adopted screening values.

Asbestos was not detected in soils sampled within this AEC.

*Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.b of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Chlorinated hydrocarbons including cis-1,2-dichloroethene, trichloroethene and tetrachloroethene were detected above the laboratory LOR in VB\_MW02, however all concentrations were below the adopted screening values.

Phenol was detected in VB\_MW03 above the laboratory LOR however the concentration detected was below the adopted screening values.

Measured concentrations of PFOS and PFOA were detected groundwater samples collected from VB\_MW01 and VB\_MW02. The concentrations of PFOA were below the adopted screening value. The concentrations of PFOS in groundwater at VB\_NW02 exceeded the adopted human health screening value.

*Discussion*

No exceedances of the adopted human health screening values were identified in soil samples collected from within this AEC.

The adopted ecological screening value for TRH C<sub>10</sub>-C<sub>16</sub> (excluding naphthalene) was exceeded in one soil sample collected from within this AEC at VB\_MW01. The ground surface at VB\_MW01 is covered in concrete hardstanding and this area is used for miscellaneous operational activities, including the storage of skip bins and spare parts. On this basis, TRH impact in this area is not considered to represent a significant risk to the terrestrial environment.

Measured concentrations of TRH, chlorinated hydrocarbons, phenol and PFOS were reported above the laboratory LOR in groundwater samples from the AEC. The concentrations did not exceed the adopted screening values, with the exception of PFOS at VB\_MW02 which exceeded the adopted human health (drinking water) screening value. On the basis that groundwater is not extracted for potable use within the vicinity of the operational area of the Site, this identified PFOS impact is not considered to represent a significant risk to human health .

It is noted that the source of the TRH, chlorinated hydrocarbon and PFOS impact was not identified during this assessment and that the presence of underground and overhead services prevented the installation of sampling locations within this AEC and limited the installation of sampling locations around the boundaries of this AEC. It is therefore considered possible that further TRH, chlorinated hydrocarbon and PFOS impacts may be present within the former A Station area.

### 5.3.3

#### *VC - Transformer Area*

The Transformer Area is located to the north west of the B Station Power Block, adjacent to the inlet canal for the Power Station. There are four transformer vessels present on the Site, containing significant quantities of insulating oil. Spare transformers 1 and 2 and the temporary turbine oil storage ASTs, with a capacity of 115 000 L are also located immediately to the east of the transformer vessels. Refuse oil storage AST No. 2, with a capacity of 35 000 L is also located to the east of the transformer vessels. The AEC is entirely covered by a concrete hardstand, with a thickness of approximately 600 mm to withstand the weight of the transformers.

Due to the age of the facility, PCB additives would have historically been used in insulating oils in transformers, capacitors and light fittings within the main operational areas. Data room documents indicate that low concentrations of PCBs (up to 4.1 µg/g) were detected in transformer oil samples collected from the vessels by Aurecon in 2012 and 2013.

In November 2006 the Vales Point Unit 6A 330/22kV Generator Transformer failed, resulting in an explosion and fire. A large volume of water and fire retardants were reported to have been used in the emergency operations associated with this event. This event is likely to have released transformer oil to the surrounding area. The potential use of firefighting foam during this fire also indicates that PFOS and/or PFOA are also COPCs.

No soil or groundwater investigations are known to have been undertaken to date which specifically target the Transformer Area. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

*AEC Investigation Methodology and Field Observations*

A total of four soil investigation bores, all of which were completed as groundwater monitoring wells, were advanced within this AEC, and two surface soil samples were collected, to assess potential impacts to soil and groundwater.

Three groundwater monitoring wells were located at the eastern end of the transformer AEC, targeting COPCs of the historical transformer fire and the off-site migration of materials and one groundwater monitoring well was located to the western end of the transformer AEC. The distribution of sampling locations is presented in *Figure 6.5 of Annex A*. Relevant borehole logs are presented within *Annex D*.

No field indicators of contamination, such as staining or odours, were noted within this AEC. No staining or unusual odours were detected through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis did not exceed 2.5 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

Field observations during the drilling works are summarised in *Table 5.4*.

**Table 5.4** *Field Observations Summary - AEC VC*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm)
VC_MW01	6.3	None	0-0.4
VC_MW02	4	H2S odour at 4.2 m bgl	0-2.5
VC_MW04	4	None	0-1.3
VC_MW05	4	None	0-1.9
VC_SB03	0.1	None	0

Groundwater field parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*. Electrical conductivity measurements indicated fresh water conditions at monitoring wells VC\_MW01, VC\_MW04 and VC\_MW05 and saline conditions were encountered within the north eastern location VC\_MW02. Moderately acidic to neutral groundwater conditions were recorded in this AEC (pH of 4.81 - 5.86).

No indications of contamination, such as sheen or odours, were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3 of Annex B*.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.c, Annex B*.

Measured concentrations of COPCs were below the adopted human health and ecological screening values in all soil samples collected from within this AEC. Measured concentrations of various heavy metals exceeded the corresponding laboratory LOR in a number of soil samples collected from within this AEC however all concentrations were below the adopted screening values. TRH was also reported at a concentration above the laboratory LOR in VC\_MW03 at a depth of 0.1 m bgl, however the concentration was below the adopted ecological and human health screening values.

Concentrations of PFOS were detected above the laboratory LOR in three soil samples at VC\_MW02 at a depth of 0.5 m bgl, VC\_MW05 at a depth of 1 m bgl and VC\_SB03 at a depth of 0.1 m bgl, however all concentrations were below the adopted ecological and human health screening values. The measured concentrations of asbestos fines and fibrous asbestos (0.005 %w/w) in the soil sample from VC\_MW03 at a depth of 0.1 m bgl exceeded the adopted human health screening value of 0.001 %w/w).

Chrysotile asbestos detected in one soil samples from this AEC at VC\_MW03 at a depth of 0.1 m bgl and the laboratory report identified "one piece of friable asbestos cement sheeting approximately 8 x 7 x 2mm".

#### *Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.c of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of the majority of COPCs were below the laboratory LOR in all groundwater samples collected from within this AEC with the exception of some metals.

PFOS was not detected in groundwater within this AEC.

#### *Discussion*

No exceedances of the adopted ecological or human health screening values were identified in soil samples collected from within this AEC with the exception of asbestos fines and fibrous asbestos in one shallow soil sample at VC\_MW03 at a depth of 0.1 m bgl. These asbestos impacts are located in an area of open ground and may represent a risk to the health of employees if potential exposure pathways are not managed appropriately.

Exceedances of the adopted screening levels identified within this AEC were limited to metals, as discussed in *Section 5.4*.

### **5.3.4 VD – Main Dangerous Goods Store**

#### *Background*

The Main Store compound is located on the south western edge of the operational area of the Power Station and comprises of a covered section and an open lay-down area covered in concrete hardstand. This area is used for storage of various materials used throughout the Power Station, including dangerous goods.

The Main V1 Store Building houses minor quantities (< 200 L) of flammable liquids and oils in cabinets. An outdoor compound area is located to the south of the Main Store and has a roofed enclosure used to house drums of lubricants and greases. A storage area located within a brick structure to the south east of the Main Store is used to house gases and corrosive liquids.

No soil or groundwater investigations are known to have been completed within this AEC to date. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

#### *AEC Investigation Methodology and Field Observations*

A total of seven soil investigation bores, five of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater. The sampling locations within this AEC are presented on *Figure 6.5* of *Annex A*. Relevant borehole logs are presented within *Annex D*.

During the sampling process, no field indicators of contamination, such as staining or odours were detected within this AEC however a slight sulfurous odour was detected in VD\_MW05. No staining or unusual odours were detected at any depth through the sampled soil profile.

Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 6.3 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.5*.

**Table 5.5** *Field Observations Summary - AEC VD*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v - isobutylene equivalents)
VD_MW01	3.5	None	0-1.2
VD_MW02	3.5	None	0-6.3
VD_MW03	3.5	None	0-1.1
VD_MW04	4	None	0-0.9
VD_MW05	6.3	Sulfur odour	0-5.9
VD_SB02	3.0	None	0-1.3

Groundwater samples were collected from five groundwater monitoring wells within the Main Dangerous Goods Store Area AEC. Groundwater parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*.

Electrical conductivity (EC) ranged from 37100  $\mu\text{S}/\text{cm}$  in VD\_MW01, to 3806  $\mu\text{S}/\text{cm}$  in VD\_MW03 indicating saline groundwater conditions. pH levels were indicative of acidic conditions within all wells with a pH ranging between 4.32 and 5.32. No evidence of hydrocarbon impact was detected in groundwater however a slight sulfurous odour was detected during the gauging in VD\_MW05.

No indications of contamination such as sheens or odours were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3 of Annex B*.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.d of Annex B*.

Measured concentrations of all COPCs were below the adopted screening values in all soil samples collected from within this AEC. The majority of measured concentrations were below the corresponding laboratory LOR. Concentrations of various heavy metals were above the corresponding laboratory LORs in a number of soil samples collected from within this AEC however all concentrations were below the adopted screening values.

Asbestos was not detected in soils sampled from within this AEC.

*Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.d of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of the majority of the COPCs were below the laboratory LOR in all groundwater samples analysed. The exceptions to this were some detection of metals (discussed in *Section 5.4*) and phenol. Concentrations of total phenols were detected at VD\_MW03 above the laboratory LOR, however the detected concentration was below the adopted ecological screening value.

*Discussion*

No exceedances of the adopted ecological or human health screening values were identified in soil samples collected from within this AEC.

Exceedances of the adopted screening levels identified within this AEC were limited to metals, as discussed in *Section 5.4*

**5.3.5 VE – Contaminated Water Treatment Plant***Background*

The Contaminated Water Treatment Plant treats the water captured by the contaminated water drainage system at the Power Station. Water entering the facility could potentially contain a range of contaminants including fuels, lubricants, chemicals, coal and ash.

All the elements of the Contaminated Water Treatment Plant are located to the north east of the operational area near the inlet canal within a grassed area. The facility comprises a sedimentation basin with an oil skimmer ('hairy ropes') and a separate secondary oil water separation section. Waste generated in the facility is understood to be trucked from the Site by an appropriately licensed contractor for offsite disposal at a licensed facility.

After passing through the oil-water separator, water discharges into a retention basin (the Chain Valley Retention Basin), located immediately to the north east. The Chain Valley Bay Retention Basin contains a series of booms to further isolate oil that may enter the pond. Water from the pond enters a pit before discharge into Chain Valley Bay. The pit contains isolation valves and the outlet pipe is covered with a membrane filter as a final screen for oil and other detritus.

Visual inspection of the Contaminated Water Treatment Plant during ERM's Phase 1 site visit in December 2013 identified an oily layer of Light Non-Aqueous Phase Liquid (LNAPL) on the water within the sediment basin. While oily residue was not observed in the holding pond, dissolved phase impact may still be present in water held within the pond.

No soil or groundwater investigations are known to have been undertaken to date which specifically target the Contaminated Water Treatment Plant. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

*AEC Investigation Methodology and Field Observations*

A total of three soil investigation bores, two of which were completed as groundwater monitoring wells, and one surface soil were advanced within this AEC to assess potential impacts to soil and groundwater.

The sampling locations within this AEC are presented on *Figure 6.5 of Annex A*. Relevant borehole logs are presented within *Annex D*.

During the sampling process, no field indicators of contamination, such as staining or odours were detected within this AEC. No staining or unusual odours were detected at any depth through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 1.3 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.6*.

**Table 5.6** *Field Observations Summary - AEC VE*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v - isobutylene equivalents)
VE_MW01	0.2	None	0
VE_MW02	4.0	None	0
VE_MW03	4.0	None	0-1.0
VD_SB02	3.0	None	0-1.3

Groundwater samples were collected from two groundwater monitoring wells within the Contaminated Water Treatment Plant AEC. Groundwater parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*.

Electrical conductivity (EC) ranged from 1113  $\mu\text{S}/\text{cm}$  in VE\_MW03, to 3152  $\mu\text{S}/\text{cm}$  in VE\_MW02 indicating slightly saline groundwater conditions. ORP measurements (mV) were within the expected range and pH levels were indicative of acidic conditions within both wells (pH of 4.26 at VE\_MW02 and 4.33 at VE\_MW03).

No indications of contamination such as sheens or odours were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3 of Annex B*.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.e of Annex B*.

Measured concentrations of all COPCs were below the adopted screening values in all soil samples collected from within this AEC. The majority of measured concentrations were below the corresponding laboratory LOR.

Concentrations of various heavy metals were above the corresponding laboratory LORs in a number of soil samples collected from within this AEC however all concentrations were below the adopted screening values.

#### *Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.e of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of the majority of the COPCs were below the laboratory LOR in all groundwater samples analysed.

The exceptions to this were some detections of metals (discussed in *Section 5.4*) and phenol. The concentrations of phenol detected above the LOR at VE\_MW02 were below the adopted ecological screening value.

#### *Discussion*

No exceedances of the adopted ecological or human health screening values were identified in soil samples collected from within this AEC.

Exceedances of the adopted screening levels identified within this AEC were limited to metals, as discussed in *Section 5.4*

### 5.3.6 VF - Waste Oil Storage

#### *Background*

Waste oil in drums and containers and oily rags are stored in the waste oil collection area to the south of the oil and grit trap and AEC VE. This area also temporarily stores new oil drums for use in the Power Station. The area is bunded and collected stormwater from this area is pumped into the Contaminated Water Treatment Plant.

During the Stage 2 ESA field works the grate in the corner of the bunded area was observed to be covered in oil. Delta indicated that this waste oil collection/storage sump is fitted with a level sensor. When the sump is 50% full the water is decanted from the bottom and sent to the oil and grit trap and the oil disposed by Delta's waste collection contractor as required. The sump level is also monitored during routine inspections.

The area immediately surround the waste oil storage area is a combination of open ground and hardstanding. The inlet canal is approximately 30 m to the west and Chain Valley Bay is approximately 150 m to the north.

No soil or groundwater investigations are known to have been undertaken to date which specifically target the Waste Oil Storage area. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

#### *AEC Investigation Methodology and Field Observations*

A total of three soil investigation bores, all of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater. The sampling locations within this AEC are presented on *Figure 6.5 of Annex A*. Relevant borehole logs are presented within *Annex D*.

During the sampling process, no field indicators of contamination, such as staining or odours were detected within this AEC. No staining or unusual odours were detected at any depth through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 0.9 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.7*.

**Table 5.7** *Field Observations Summary - AEC VF*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v - isobutylene equivalents)
VF_MW01	6.0	None	0-0.8
VF_MW02	3.7	None	0
VF_MW03	6.5	None	0-0.9

Groundwater samples were collected from three groundwater monitoring wells within the Waste Oil Storage AEC. Groundwater parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*.

Electrical conductivity (EC) ranged from 540-1126  $\mu\text{S}/\text{cm}$  indicating fresh to brackish groundwater conditions. pH measurements ranged from pH 5.12 to 5.85, and were indicative of slightly acidic groundwater conditions.

No indications of contamination such as sheens or odours were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3 of Annex B*.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.f of Annex B*.

Measured concentrations of COPCs were below the adopted human health screening values in all soil samples collected from within this AEC.

Measured concentrations of COPCs were below the adopted ecological screening values in all soil samples collected from within this AEC with the exception of soil collected from VF\_MW02 at a depth of 0.1 m bgl which exceeded the ecological screening value for zinc.

Measured concentrations of various heavy metals were above the corresponding laboratory LOR in a number of soil samples collected from within this AEC however, with the exception of zinc, all concentrations were below the adopted screening values. Concentrations of PAHs were also reported above the laboratory LOR at VF\_MW02 at a depth of 0.1 m bgl (duplicate sample) however the concentration was below the adopted screening value.

*Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.f of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of the majority of the COPCs were below the laboratory LOR in all groundwater samples analysed. The exceptions to this were some detections of metals.

*Discussion*

No exceedances of the adopted human health screening values were identified in soil samples collected from within this AEC.

Zinc concentrations marginally exceeded adopted ecological screening values in shallow soil sampled from 0.1 m bgl at VF\_MW02. It is noted that the concentration of zinc in the deeper soil sample collected from 2.0 m bgl at this location was below the adopted ecological screening values, and the exceedance at 0.1 m bgl may be attributed to shallow fill material at this location. This AEC is within the fenced operational area and therefore use of the area by wildlife is limited. The groundcover within this AEC is a mix of hardstanding and areas of grass cover. On this basis, these marginal exceedances are therefore considered unlikely to represent a significant risk to the terrestrial environment assuming ongoing commercial industrial use in the current or similar configuration.

**5.3.7*****VG - Fuel Oil Installation****Background*

The Fuel Oil Installation comprises two 1.2 ML steel ASTs, which are used for the storage of diesel. This installation is located outside the station inner security fencing and the bulk fuel oil supplies are delivered by road tanker. The volume of fuel being stored and transferred from this facility to the Site represents a significant source of potential contamination.

The ASTs are bunded with drainage from the bund discharging to the No. 1 Settling Basin for disposal to the Ash Dam.

Delta personnel indicated that the fuel within this system is reconciled on a monthly basis and a formal stocktake conducted every 6 months as part of the fuel accounting procedure. Given the limitations of wet stock reconciliation when dealing with such large volumes, there is a potential for leaks or spills to have caused the migration of contaminants to the underlying soil and groundwater.

No soil or groundwater investigations are known to have been undertaken to date which specifically target the Fuel Oil Installation. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

*AEC Investigation Methodology and Field Observations*

A total of four soil investigation bores, all of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater. The sampling locations within this AEC are presented on *Figure 6.5 of Annex A*. Relevant borehole logs are presented within *Annex D*.

During the sampling process, no field indicators of contamination, such as staining or odours were detected within this AEC. No staining or unusual odours were detected at any depth through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 34.0 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.8*.

**Table 5.8** *Field Observations Summary - AEC VG*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v -isobutylene equivalents)
VG_MW01	14.8	None	0-1.2
VG_MW02	9.0	None	0
VG_MW03	10	Hydrocarbon staining, slight hydrocarbon odour	0-34.0
VG_MW04	14	None	0-3.5

Groundwater samples were collected from four monitoring wells within the Fuel Oil Installation AEC. Groundwater parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*.

Electrical conductivity (EC) ranged from 213.8 - 4419  $\mu\text{S}/\text{cm}$  indicating fresh to saline groundwater conditions. pH levels were indicative of acidic conditions within the four wells and VG\_MW02 demonstrated a pH of 3.89 which is quite acidic and may be indicative of acid sulfate soil conditions in this area.

No indications of contamination such as sheens or odours were observed during groundwater sampling within this AEC, however sheen was observed during the initial purging of VG\_MW02 and VG\_MW04. A summary of field observations from the groundwater sampling works are presented within *Table 3 of Annex B*.

*Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.g of Annex B*.

Measured concentrations of COPCs were below the adopted human health screening values in all soil samples collected from within this AEC.

Measured concentrations of COPCs were below the adopted ecological screening values with the exception of TRH C<sub>10</sub>-C<sub>16</sub> (excluding naphthalene) in the soil sample collected from VG\_MW03 at a depth of 0.5 m bgl and benzo(a)pyrene in the soil sample collected from VG\_MW01 at a depth of 0.1 m bgl. Measured concentrations of various heavy metals were above the corresponding laboratory LOR in a number of soil samples collected from within this AEC, however all concentrations were below the adopted screening values.

*Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.g of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of all COPCs were below the laboratory LOR in all groundwater samples analysed, with the exception of metals (discussed in *Section 5.4*).

*Discussion*

No exceedances of the adopted human health screening values were identified in soil samples collected from within this AEC.

The measured concentration of TRH C<sub>10</sub>-C<sub>16</sub> exceeded the adopted ESL in the soil sample collected from VG\_MW03 at a depth of 0.5 m bgl and the measured concentration of benzo(a)pyrene exceeded the adopted ESL in the soil sample collected from VG\_MW01 at a depth of 0.1 m bgl. These sampling locations are located on the eastern and northern side of the AST bund beneath concrete hardstand, and the vegetation in this area is limited to patchy grass and some isolated trees on adjacent areas of open ground. No obvious signs of stressed vegetation were noted in the adjacent vegetated areas. These impacts are therefore considered unlikely to represent a significant risk to the terrestrial environment under the ongoing use of the Site as a power station.

5.3.8

**VH – Vehicle Refuelling Depot**

*Background*

The Vehicle Refuelling Depot is located adjacent to the Administration Building and consists of two Underground Storage Tanks (USTs) which are used to store unleaded petrol and diesel and are connected to two bowzers.

Anecdotal evidence from Delta personnel indicated that a single decommissioned underground storage tank is also located approximately 10 m to the north of the operational refuelling facilities and two decommissioned underground storage tanks and bowser plinth are located approximately 30 m north-west of the operational refuelling facilities. Tank integrity test data was not available for review.

The area is sealed to allow vehicles and heavy machinery such as cranes to refuel. The area is also a thoroughfare to the main operational areas of the Site.

Soil and groundwater investigations have been completed in the areas of underground tank infrastructure to facilitate compliance with relevant UPSS legislation. Four groundwater monitoring wells were installed in the UPSS area in 2010 and an additional six wells were installed in 2011.

In 2010, TRH(C<sub>10</sub> – C<sub>36</sub>) was identified at a concentration of 2540 µg/L, in a well installed to the north of the UPSS but TRH was not detected in any of the 10 wells sampled in 2011 (DLA Environmental, 2012). In 2011, four new groundwater monitoring wells were installed by David Lane and Associates and these have been subsequently assessed for the presence/absence of hydrocarbon sheen using an interface probe. Hydrocarbon sheens were not detected in these investigations (David Lane and Associates, 2013).

*AEC Methodology and Investigation Field Observations*

Ten existing groundwater monitoring wells were gauged and sampled during the Phase 2 ESA. Due to the presence and coverage of the existing wells around the active and decommissioned UST's, ERM did not undertake additional well installation within the area. The sampling locations within this AEC are presented on *Figure 6.5 of Annex A*.

A summary of the field observations from the drilling works are presented within *Table 5.9*.

**Table 5.9 Groundwater Field Observations Summary – AEC VH**

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence
VH_X_MW01	5.18	None
VH_X_MW02	5.42	None
VH_X_MW03	5.21	None
VH_X_MW04	5.21	None
VH_X_MW05	3.51	None

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence
VH_X_MW06	3.30	None
VH_X_MW07	4.34	None
VH_X_MW08	3.28	None
VH_X_MW09	3.38	None
VH_X_MW10	3.51	None

Groundwater samples were collected from the 10 existing groundwater monitoring wells present within the AEC. Groundwater parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*. Field parameters indicated typically brackish groundwater conditions with electrical conductivity ranging from 1337 to 7064  $\mu\text{S}/\text{cm}$ .

pH measurements in groundwater within this AEC ranged between 3.32 and 4.35 indicating acidic conditions, which may be indicative of the presence of acid sulfate soil conditions in this area.

No indications of contamination such as sheens or odours were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3 of Annex B*.

#### *Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.h of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of the majority of COPCs were below the laboratory LOR, with the exception of metals in most groundwater monitoring wells (discussed below), benzene at VH\_X\_MW06 and TRH, BTEX and phenols at VH\_X\_MW08. The concentration of benzene in groundwater at VH\_X\_MW06 exceeded the adopted human health (drinking water) screening values. The concentrations of TRH C<sub>6</sub>-C<sub>10</sub> (less BTEX), phenols, toluene, ethylbenzene and xylene in groundwater at VH\_X\_MW08 were above the laboratory LOR; however all concentrations were below the adopted human health and ecological screening values. The concentration of benzene at VH\_X\_MW08 exceeded both the human health (drinking water) and human health (recreational) screening values.

*Discussion*

Benzene was reported at concentrations exceeded the adopted human health (drinking water) screening values in two groundwater monitoring wells (VH\_X\_MW06 and VH\_X\_MW08) within this AEC. The adopted human health (recreational) screening value for benzene was also exceeded at VH\_X\_MW08). It is considered likely that the benzene impacts in AEC VH are associated with the presence of USTs in this area.

Groundwater monitoring has been ongoing within AEC VH since 2010, when TRH(C<sub>10</sub> - C<sub>36</sub>) was identified at a concentration of 2540 µg/L, in a well installed to the north of the USTs. Hydrocarbon detections in the current assessment were limited to BTEX constituents and do not suggest the presence of a significant ongoing release in this area of the Site.

The inferred groundwater flow direction in the area of the Vehicle Refuelling Depot is north east below the former A Station Power Block towards the inlet/outlet canal. In the absence of potable groundwater use in this area of the Site, these impacts are not considered to represent a significant potential risk to human health under the ongoing use of the Site as a Power Station. Benzene impacts were also not identified in sediment or surface water samples collected from the mouth of the inlet/outlet canal, indicating that these impacts are unlikely to be impacting upon recreational users of Lake Macquarie.

**5.3.9*****VI - Water Treatment Plant Area****Background*

The Demineralisation Plant, Reverse Osmosis Plant and Polisher Regeneration Plant are located to the south west of the B Station Power Block. Significant quantities of sulfuric acid, sodium hydroxide, hypochlorite, ammonia and ferric sulfate are stored in ASTs in this area.

The water treatment plant area is bunded with the surrounding area consisting of concrete hardstand. The water treatment plant is confined by the former A Station to the north, and the Power Station access road utilised by vehicles and heavy plant to the south followed by a steep embankment up towards the Fly Ash Plant (AEC VT).

No soil or groundwater investigations are known to have been undertaken to date which specifically target the Water Treatment Plant Area. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

*AEC Methodology and Investigation Field Observations*

A total of three soil investigation bores, two of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater. The sampling locations within this AEC are presented on *Figure 6.5*. Relevant borehole logs are presented within *Annex D*. For the purpose of discussion of groundwater results, monitoring wells from VA, VB and VH have been considered where they are located around the perimeter of this AEC, to identify COPC that may have migrated from this AEC.

No field indicators of contamination, such as staining, odours or visibly stressed vegetation were noted within this AEC. No staining or unusual odours were detected at any depth through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 0.6 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.10*.

**Table 5.10** *Field Observations Summary*

AEC VIBorehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm)
VI_MW01	3.9	None	0-0.6
VI_MW02	4	None	0
VI_SB01	0.1	None	0

Groundwater field parameter measurements collected during the groundwater sampling works are presented in *Table 3* of *Annex B*. Electrical conductivity measurements indicated fresh water conditions at VI\_MW02 and brackish groundwater conditions at VI\_MW01. pH measurements indicated acidic conditions at VI\_MW01 (pH 4.2) and slightly acidic conditions at VI\_MW02 (pH 5.39) and moderately acidic pH values.

No indications of contamination, such as sheen or odours, were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3* of *Annex B*.

*Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.i* of *Annex B*.

Measured concentrations of all COPCs with the exception of zinc (discussed below) were below the adopted human health and ecological screening values in all soil samples collected from within this AEC. The majority of measured concentrations were below or close to the corresponding laboratory LOR.

Concentrations of some TRH fractions were above the corresponding laboratory LOR in soil collected from VI\_SB01 at a depth of 0.1 m bgl; however all concentrations were below the adopted screening values.

Concentrations of various heavy metals were identified above the corresponding laboratory LOR in a number of soil samples collected from within this AEC. All concentrations of COPC in soil were below the adopted human health and ecological screening values, with the exception of zinc at VI\_SB01 at a depth of 0.1 m bgl which exceeded the adopted ecological screening value.

#### *Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.i of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of the majority of the COPCs were below the laboratory LOR in all groundwater samples analysed with the exception of metals, TRH and PFOS. Measured concentrations of TRH C<sub>16</sub>-C<sub>34</sub> and PFOS were detected above the laboratory LOR at VI\_MW01, however all detected concentrations were below the adopted screening values.

Cobalt, copper and zinc were detected at concentrations exceeded the adopted ecological screening values in groundwater samples collected from monitoring wells within this AEC. Manganese was detected at concentrations exceeded the adopted human health (drinking water) in groundwater samples collected from several monitoring wells within this AEC.

#### *Discussion*

No exceedances of the adopted human health screening values were identified in soil samples collected from within this AEC. The ecological screening value for zinc was exceeded by a factor of approximately 300% in one soil sample collected from VI\_SB01 at a depth of 0.1 m bgl.

This sampling point is located in a strip of open ground within the operational area that is approximately 20 m in width. The vegetation in this area is limited to a covering of grass and isolated trees. Given the highly disturbed and operational nature of the Site, this isolated area of zinc impact is not considered to represent a significant risk to the terrestrial environment under the ongoing commercial industrial use of the Site.

**5.3.10 VJ – Coal Storage Area**

*Background*

The coal storage area is located to the south west of the power block and is used for stockpiling of coal prior to transfer via conveyor to the coal mill and boilers. Truck washing facilities are located within this area and it is understood that biomass (primarily wood chips) for electricity generation were historically stored within this AEC.

Potential contamination sources include dirty water from the truck washing facility and contaminated stormwater runoff from this area, which are captured by a system of concrete drains that discharge into the settling ponds located in the northern portion of the stockpile area. Water from the retention ponds is discharged to the Ash Dam and overflow from these settling ponds is discharged into the outfall canal. Leaching of contaminants from the coal stockpiled on open ground may also impact groundwater.

No soil or groundwater investigations are known to have been completed within this AEC to date, therefore further investigation was undertaken to provide a baseline for soil and groundwater conditions in this area.

*AEC Methodology and Investigation Field Observations*

A total of fourteen soil investigation bores, ten of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater. The distribution of sampling locations within this AEC is presented in *Figure 6.5 of Annex A*. Relevant borehole logs are presented within *Annex D*.

No field indicators of contamination, such as staining, odours or visibly stressed vegetation were noted outside of the coal stockpile area within this AEC. No staining was detected at any depth through the sampled soil profile but a sulfurous or organic odour was noted in a number of deep soil samples. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 15.2 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.11*.

**Table 5.11 Field Observations Summary – AEC VJ**

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm)
VJ_MW01	7.5	None	0
VJ_MW02	5	None	0-2.6
VJ_MW03	6.3	Sulfur odour at 4 m bgl	0-15.2
VJ_MW04	7	None	0-10.5
VJ_MW05	8	None	0-2.7
VJ_MW06	8	None	0.2-5.1

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm)
VJ_MW07	8	None	0
VJ_MW08	6	None	0-0.8
VJ_MW09	6	None	0.2-6.1
VJ_MW10	6	Organic odour	0.2-6.1
VJ_SB01	3	None	0-1.1
VJ_SB02	3	Organic odour	0-2.6
VJ_SB03	3	None	0.2-3
VJ_SB04	3	None	0.2-3

Groundwater field parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*. Electrical conductivity measurements ranged from 529 to 3049  $\mu\text{S}/\text{cm}$ , indicating fresh water to saline conditions. The pH of the groundwater ranged from 4.32 to 6.11, which indicates slightly acidic to acidic conditions in groundwater across the AEC, this, in combination with the sulfurous odours noted may be an indicator of acid sulfate soil conditions.

No indications of contamination, such as sheen or odours, were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3 of Annex B*.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.j of Annex B*.

Measured concentrations of COPCs were below the adopted human health screening values in all soil samples collected from within this AEC.

The majority of measured concentrations in soil were below the corresponding laboratory LOR with the exception of toluene, PAHs and some TRH fractions. The concentration of toluene was above the corresponding laboratory LOR in soil collected from VJ\_MW03 at a depth of 4.0 m bgl; however all concentrations were below the adopted screening values.

Concentrations of PAHs were above the corresponding laboratory LOR in soil collected from VJ\_SB04\_0.15 m bgl, VJ\_SB01\_1.0 m bgl, VJ\_MW08\_1.0 m bgl, VJ\_MW07\_0.1 m bgl, VJ\_MW01\_0.2 m bgl, VJ\_MW05\_1.0; however all concentrations were below the adopted screening values.

Concentrations of some TRH fractions were above the corresponding laboratory LOR in soil collected from VJ\_SB04 at a depth of 0.15 m bgl, VJ\_SB01 at a depth of 1.0 m bgl, VJ\_MW08 at a depth of 1.0 m bgl, VJ\_MW01 at a depth of 0.2 m bgl. however all concentrations were below the adopted screening values.

All concentrations were below the adopted screening values with the exception of TRH C<sub>10</sub>-C<sub>16</sub> at VJ\_MW07 at a depth of 0.1 m bgl which marginally exceeded the adopted ecological screening value.

Concentrations of various heavy metals were identified above the corresponding laboratory LOR in a number of soil samples collected from within this AEC. All concentrations of COPC in soil were below the adopted human health and ecological screening values.

#### *Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.j of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of the majority of the COPCs were below the laboratory LOR in all groundwater samples analysed with the exception of some TRH fractions, toluene and 3&4-methylphenol at VJ\_MW03 and metals in groundwater across the AEC (discussed in *Section 5.4*). The concentrations of TRH, toluene and 3&4-methylphenol at VJ\_MW03 were above the corresponding laboratory LOR however all concentrations were below the adopted screening values.

#### *Discussion*

No exceedances of the adopted human health screening values were identified in soil samples collected from within this AEC. The ecological screening value was exceeded in one soil sample at VJ\_MW07.

The measured concentration of TRH C<sub>10</sub>-C<sub>16</sub> marginally exceeded the adopted ecological screening value in the soil sample collected from VJ\_MW07 at a depth of 0.1 m bgl. The concentration of TRH in soil was below the adopted human health screening values and TRH was not detected above the laboratory LOR in groundwater at this location. The concentrations of TRH reported in other sampling locations within this AEC did not exceed the adopted screening values. Monitoring well VJ\_MW07 was located on the south-western corner of the coal stockpile area approximately 20 m from the edge of the coal stockpile area in an area of unsealed ground around the coal stockpile.

The vegetation in this area is limited to sparse areas of grass but no obvious differences were noted between the vegetation within this TRH impacted area and other similar sampling locations around the Coal Stockpile. On this basis and considering that exceedances of the adopted screening values were not identified in the other soil samples collected from within this AEC, this identified TRH impact is not considered to represent a significant risk to the terrestrial environment under the ongoing use of the Site as a Power Station.

### 5.3.11 VK – Mobile Plant Maintenance and Refuelling Areas

#### *Background*

Mobile plant associated primarily with the coal storage area is serviced and refuelled in AEC VK, located directly to the north of the coal storage area. This area also houses a diesel AST, refuse oil AST, a lubricants station and a parts cleaning facility.

The refuelling/ maintenance facilities are contained within a bunded area and runoff from this area is directed via an oil separator into a settling pond.

No soil or groundwater investigations are known to have been undertaken to date which specifically target the Mobile Plant Maintenance Area. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

#### *AEC Methodology and Investigation Field Observations*

A total of nine soil investigation bores, seven of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater. The sampling locations were distributed within this AEC as presented on *Figure 6.5 of Annex A*. Relevant borehole logs are presented within *Annex D*.

Field indicators of contamination, such as staining, odours or visibly stressed vegetation were not noted within this AEC. No staining or unusual odours were detected at any depth through the sampled soil profile at other locations within this AEC. Measured concentrations of ionisable volatile compounds via headspace analysis did not exceed 10.3 ppm v (isobutylene equivalent) in soil samples collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.12*.

**Table 5.12** *Field Observations Summary – AEC VK*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v)
VK_MW01	8	None	0-0.2
VK_MW02	6	None	0-1.3
VK_MW03	6	None	0-1.1
VK_MW04	6	None	0.1-0.4
VK_MW05	8.3	None	0-10.3
VK_MW06	7	None	0-1.3
VK_MW07	5.4	None	0-0.1
VK_SB01	5.1	None	0-0.9
VK_SB02	3.9	None	0

Field parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*. Electrical conductivity measurements indicated generally fresh groundwater conditions with brackish conditions at VK\_MW05, VK\_MW06 and VK\_MW07 (2648 to 6141  $\mu\text{S}/\text{cm}$ ). The groundwater within this AEC was slightly acidic to acidic with a pH range between 4.12 and 5.44.

Sheen was observed on groundwater purged from VK\_MW03 during the groundwater sampling event. No other indications of potential contamination, such as sheen or odours, were observed during groundwater sampling at other locations within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3 of Annex B*.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.k of Annex B*.

Measured concentrations of COPCs were below the adopted human health screening values in all soil samples collected from within this AEC. Measured concentrations of COPCs were below the adopted ecological screening values in all soil samples collected from within this AEC with the exception of nickel in the soil sample collected from VK\_MW04 at a depth of 0.2 m bgl.

The majority of measured concentrations of COPCs were below the corresponding laboratory LOR. Concentrations of some TRH fractions were above the corresponding laboratory LOR in the soil sample collected from VK\_MW07 at 1.0 m bgl, however all concentrations were below the adopted screening values. Concentrations of phenanthrene were above the corresponding laboratory LOR in the soil samples collected from VK\_MW02 at a depth of 0.2 m bgl, VK\_MW04 at a depth of 0.2 m bgl, VK\_MW06 at a depth of 0.5 m bgl and VK\_MW07 at a depth of 1.0 m bgl, however all concentrations were below the adopted screening values.

#### *Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.k of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of the majority of the COPCs were below the laboratory LOR in all groundwater samples analysed, with the exception of selected metals in groundwater (discussed in *Section 5.4*).

*Discussion*

No exceedances of the adopted human health screening values were identified in soil samples collected from within this AEC. The ecological screening value for nickel was exceeded in the soil sample collected from VK\_MW04 at a depth of 0.2 m bgl. This soil sample was collected below concrete hardstanding and therefore the identified exceedance for nickel is not considered to represent a significant risk to the terrestrial environment under the ongoing use of the Site as a Power Station.

### 5.3.12 *VL - Sewage Treatment Plant*

*Background*

The Vales Point Sewage Treatment system is located outdoors to the west of the operational area and consists of a tank with sedimentation compartment and sludge compartments and three treatment ponds, with a mechanical aeration system. The effluent from the third pond in this system ultimately discharges to the Retention Basin on the northern side of the Ash Dam.

Sewage can contain a variety of contaminants, including nitrates, metals, trace concentrations of toxic chemicals and salts. Potential contamination sources in association with the sewage treatment plant include leakage from the sewage treatment systems, associated pipework or retention basin into the underlying soil or groundwater.

No soil or groundwater investigations are known to have been completed in the vicinity of the sewage treatment plant facilities, therefore further investigation was undertaken to assess potential environmental issues associated with soil and groundwater conditions within this AEC.

*AEC Methodology and Investigation Field Observations*

A total of three soil investigation bores, all of which were completed as groundwater monitoring wells, were advanced within this AEC and one surface soil sample was collected to assess potential impacts to soil and groundwater. The three groundwater monitoring wells were distributed across the AEC to up gradient, cross-gradient and down gradient of the sewage treatment facility. The soil bore VL\_SB01 was abandoned due to the proximity to sub-surface electrical utilities, however a surface soil sample was collected at this location. The sampling locations were distributed within this AEC as presented on *Figure 6.5 of Annex A*. Relevant borehole logs are presented within *Annex D*. No field indicators of contamination, such as staining, odours or visibly stressed vegetation were noted within this AEC. No staining or unusual odours were detected at any depth through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 0.2 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.13*.

**Table 5.13** *Field Observations Summary - AEC VL*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm)
VL_MW01	6	None	0- 0.2
VL_MW02	7	None	0-0.1
VL_MW03	6	None	0-0.1
VL_SB01	0.1	None	0

Groundwater field parameter measurements collected during the groundwater sampling works are presented in *Table 3* of *Annex B*. Electrical conductivity measurements in groundwater within this AEC were indicative of fresh water conditions, with a range between 292 and 517  $\mu\text{S}/\text{cm}$ .

The measured pH ranged between 5.36 and 6.11 which was indicative of slightly acidic groundwater conditions within this AEC.

No indications of contamination, such as sheen or odours, were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3* of *Annex B*.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.1* of *Annex B*.

Measured concentrations of COPCs were below the adopted human health and ecological screening values in all soil samples collected from within this AEC. The majority of measured concentrations of COPC were also below or close to the corresponding laboratory LOR. Concentrations of various heavy metals were identified above the corresponding laboratory LOR in a number of soil samples collected from within this AEC, however all concentrations were below the adopted screening values.

#### *Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.1* of *Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9* of *Annex A*.

Measured concentrations of the majority of the COPCs were below the laboratory LOR in all groundwater samples analysed. The exceptions to this were some detections of metals within groundwater across this AEC (discussed in *Section 5.4*).

*Discussion*

No exceedances of the adopted screening values were identified in soil samples collected from within this AEC. Similarly, with the exception of metals, no exceedances of the adopted screening values were identified in groundwater.

**5.3.13 VM - Chlorine Plant***Background*

The Vales Point Power Station generates free chlorine onsite through an electrolytic process using seawater sourced from Lake Macquarie. The chlorine plant is located to the north west of the power block and includes the bulk storage of hydrochloric acid and sodium hypochlorite in ASTs. The transformer oil storage filtration building, associated with the TransGrid Switchyard is also located immediately adjacent to the Chlorine Plant to the north.

The chlorine plant area is bunded and this AEC is predominantly covered by a concrete hardstand to allow access for vehicles and plant machinery.

No soil or groundwater investigations are known to have been completed within this AEC to date and therefore further investigation was undertaken to provide a baseline and to assess soil and groundwater conditions within this AEC. The data collected within this AEC was also used to evaluate COPCs associated with the operation of the adjacent transformer oil storage filtration building.

*AEC Methodology and Investigation Field Observations*

A total of three soil investigation bores, all of which were completed as groundwater monitoring wells, were advanced within this AEC and three surface soil samples were collected to assess potential impacts to soil and groundwater. Surface soil samples were collected at three locations. At three locations where soil bore and monitoring wells could not be advanced, as discussed in *Section 4.1*. The sampling locations were distributed within this AEC as presented on *Figure 6.5 of Annex A*. Relevant borehole logs are presented within *Annex D*.

No field indicators of contamination, such as staining or odours were noted within this AEC. No staining or unusual odours were detected at any depth through the sampled soil profile, although an organic odour was noted in one deep soil sample. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 0.5 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.14*.

**Table 5.14** *Field Observations Summary – AEC VM*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm)
VM_MW01	6	None	0-0.5
VM_MW02	0.1	None	0
VM_MW03	4.5	None	0-0.2
VM_MW04	4	Organic odour	0-0.5
VM_MW05	0.1	None	0
VM_SB01	02	None	0

Groundwater field parameter measurements collected during the groundwater sampling works are presented in *Table 3* of *Annex B*. Electrical conductivity measurements in groundwater within this AEC indicated fresh water to brackish water conditions, with a range from 895 to 3973  $\mu\text{S}/\text{cm}$ . The measured pH ranged between pH 5.08 and 6.03 which was indicative of slightly acidic groundwater conditions within this AEC.

No indications of contamination, such as sheen or odours, were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 2* of *Annex B*.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.m* of *Annex B*.

The majority of measured concentrations of COPCs were below or close to the corresponding laboratory LOR. Concentrations of TRH were identified above the corresponding laboratory LOR in soil samples collected from VM\_MW02 at a depth of 0.1 m bgl and VM\_MW05 at a depth of 0.1 m bgl,

Concentrations of PAHs including acenaphthylene, benz(a)anthracene, benzo(a) pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, chrysene, fluoranthene and pyrene were identified above the corresponding laboratory LOR in soil samples collected from VM\_MW02 at a depth of 0.1 m bgl. All reported PAH and TRH concentrations were below the adopted screening values. Concentrations of various heavy metals were identified above the corresponding laboratory LOR in a number of soil samples collected from within this AEC. The concentration of zinc in a soil sample collected from 0.2 m bgl at VM\_MW02 exceeded the adopted ecological screening value.

The measured concentrations of asbestos fines and fibrous asbestos (0.004 %w/w) in the soil sample from VC\_MW03 at a depth of 0.1 m bgl exceeded the adopted human health screening value of 0.001 % w/w). Chrysotile and amosite asbestos fines and fibrous asbestos (FA and AF) were detected in one sample at VM\_MW02 at a depth of 0.1 m bgl and the laboratory report identified “one piece of friable asbestos cement sheeting approximately 5 x 4 x 2mm plus several loose bundles of friable asbestos fibres approximately 2 x 1 x 0.5mm”.

#### *Groundwater*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.m of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*

Concentrations of some TRH fractions were detected above the corresponding laboratory LOR in groundwater from monitoring well VM\_MW04, however all concentrations were below the adopted screening values.

Concentrations of PFOS and PFOA were detected above the corresponding laboratory LOR in groundwater from monitoring well VM\_MW03. The concentration of PFOS in groundwater at VM\_MW03 was exceeded the adopted human health (drinking water) screening values.

#### *Discussion*

No exceedances of the adopted human health screening values were identified in soil samples collected from within this AEC. The ecological screening value for zinc was exceeded in the soil sample collected from VM\_MW02 at a depth of 0.1 m bgl.

VM\_MW02 is located in an operational area of open ground immediately adjacent to the outlet canal. The vegetation in this area is limited to a sparse covering of grass and there is limited access to the area by wildlife. On this basis, this area of zinc impact is not considered to represent a significant potential risk to the terrestrial environment under the ongoing use of the Site as a power station.

The measured concentrations of asbestos fines and fibrous asbestos (0.004 %w/w) in the soil sample from VC\_MW03 at a depth of 0.1 m bgl exceeded the adopted human health screening value of 0.001 % w/w). It is noted that this sample was collected from unsealed ground adjacent to the chlorine plant on the western side of the canal, and surface soils in this area may be accessible to Site workers and thus may represent a potential health risk if potential exposure pathways are not managed appropriately.

### 5.3.14 VN – Wye Coal Unloader Area and Coal Conveyors

#### *Background*

The Wye Coal Unloader facility is located to the north of the Ash Dam and adjacent to the Main Northern Rail Line between Wye and Morisset, approximately 4.5 km to the north west of the operational area. A network of coal conveyors links this facility to the Coal Storage Area (AEC VJ). The operational area of this AEC is surrounded by buffer lands primarily comprised of dense bushland.

The Wye Coal Unloader facility is comprised of a series of hoppers, feeders and transfer points. At the time of the investigation, the operation of the rail corridor and hopper unloader facility was suspended for maintenance and additional construction.

During the site investigation works, seven ASTs were identified in the operational area of the AEC. Four ASTs located near the Rail to Vales (RV) conveyor were used to hold water and three ASTs located near the office pre-fab buildings and main hopper unloader are used as fire water storage tanks and are connected to the fire hydrants servicing the operational areas and conveyor systems. Two water retention ponds are located to the north east of the main hopper unloaders.

The majority of the RV conveyor system follows ground level, with the RV conveyor gradually becoming elevated towards the transfer towers. The conveyors are covered to reduce the potential for fugitive dust emissions.

One pond of unknown historic use is located in a cleared area, approximately 600 m to the south east of the conveyor loop. This pond is not utilised by Delta and is surrounded by dense vegetation.

Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

#### *AEC Methodology and Investigation Field Observations*

A total of fifteen soil investigation bores, ten of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater. The sampling locations within this AEC are presented on *Figure 6.1* of *Annex A*. Relevant borehole logs are presented within *Annex D*.

Significant quantities of fly-tipped waste, including drummed oils, household waste, wood, steel and plastic were observed in very close proximity to drilling location VN\_MW10, on the eastern Site boundary, as shown in Photograph 47 and 48 of *Annex G*.

This area is accessible by the public via a short gravel road off Rutleys Road and the waste is likely to have been dumped illegally by members of the public.

No staining or unusual odours were detected at any depth through the sampled soil profile in this AEC. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 3.4 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.15*.

**Table 5.15** *Field Observations Summary - AEC VN*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v -isobutylene equivalents)
VN_MW01	7	None	0- 0.6
VN_MW02	4	None	0
VN_MW03	14	None	0
VN_MW05	7.5	None	0-0.9
VN_MW06	11.5	None	0-3.5
VN_MW07	11.5	None	0-1.8
VN_MW08	8	None	0-3.4
VN_MW09	7	None	0-1.6
VN_MW10	13.5	None	0
VN_MW12	5	None	0-0.2
VN_SB01	3	None	0-1.5
VN_SB02	3	None	0-0.1
VN_SB03	1.2	None	0
VN_SB04	3	None	0-0.6
VN_SB05	0.5	None	0.8-1.0

Groundwater field parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*. Electrical conductivity measurements indicated freshwater conditions in groundwater within this AEC, with a range between 172.3 and 1000  $\mu\text{S}/\text{cm}$ . The measured pH ranged between 3.52 and 6, which is indicative of acidic to slightly acidic conditions in groundwater within this AEC. Acidic groundwater conditions at VN\_MW12 (pH of 3.52) may indicate the presence of acid sulfate soil conditions in the area. This monitoring well is located immediately to the south of the water retention ponds.

No indications of contamination, such as sheen or odours, were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 2 of Annex B*.

*Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.n of Annex B*.

Measured concentrations of all COPCs with the exception of zinc were below the adopted screening values in all soil samples collected from within this AEC. The majority of measured concentrations were also below or close to the corresponding laboratory LOR in the soil samples collected from within this AEC. The zinc concentration measured in the soil sample collected from VN\_MW08 at a depth of 0.2 m bgl was marginally in excess of the ecological screening value for areas of ecological significance but did not exceed the ecological screening value for commercial/industrial areas.

*Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.n of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*

The majority of measured concentrations of COPCs in groundwater were also below or close to the corresponding laboratory LOR in the samples collected from within this AEC, with the exception of metals (discussed in *Section 5.4*).

*Discussion*

No exceedances of the adopted human health screening values were identified in soil samples collected from within this AEC. The ecological screening value was exceeded in soil at VN\_MW08 for zinc.

The zinc concentration measured in VN\_MW08 at a depth of 0.2 m bgl marginally exceeded the screening value adopted for areas of ecological significance. This sampling location was located within the operational area of this AEC. The *Delta Coast Land Management Manual* (GHD, 2012) indicated that a number of threatened bat species have been identified in the wooded areas surrounding the operational area but as the zinc concentration in this sample did not exceed the adopted screening value for commercial/industrial areas and zinc concentrations in excess of the screening levels for ecologically significant areas were not identified across the remainder of the AEC, this isolated impact is not considered to be representative of a significant risk to the terrestrial environment.

The US EPA (2013) ProUCL (version 5) software was also used to calculate a 95% UCL value of 16.7 mg/kg for the zinc concentrations in the soil samples collected at depths of less than 1 m bgl across this AEC (calculations provided in *Annex I*). This value is significantly less than the ecological screening level adopted for areas of ecological significance.

## 5.3.15

**VO – Ash Dam***Background*

The Ash Dam is located to the south-west of the operational area of the Site. A large proportion of the ash which is produced from the Vales Point Power Station is transported by wet sluicing via pipelines to the Ash Dam. The northern portion of the Ash Dam (Ponds 1, 2 and 3) have been filled to capacity and rehabilitated. The central areas of the Ash Dam, known as Pond 4, 5A and 5B, are currently active and receiving wet sluice from the Power Station. Ash settles in these upper reaches of the dam and the water is pumped back to the Power Station via ash return water pumps. Prior to Munmorah Power Station ceasing operations, the Vales Point Ash Dam was also used for the storage of fly ash produced at Munmorah Power Station.

Various other solid and liquid wastes are also permitted to be directed to the Ash Dam under the EPL including coal fines, mill pyrites, residual detergents and oil sheens, sand, concrete products, boiler blowdown, minor chemical spill residues, chemicals for environmental control, ash dam water treatment plant residues, dust returned from the ash recovery plant, marine growth, debris, seaweed, chemical cleaning solutions, oil and chemically impacted soil, desilting of settling basins, dredge spoil, waste wood, wood chips, dirty water drains, treatment plant discharges, coal handling plant stormwater, neutralised demineralisation effluent, polisher plant effluent, spent ion exchange resins, chlorine plant storage vessel precipitates, cable tunnel drainage, fabric filter bags, coal chitter and soil capping materials, coal mine dewatering discharges. Asbestos Containing Material (ACM) was also historically disposed within the dam.

Heavily vegetated areas are located around the boundaries of the Ash Dam. The *Delta Coast Land Management Manual* (GHD, 2012) indicates that threatened flora and fauna has been identified in the buffer lands surrounding the Ash Dam. *State Environmental Planning Policy No. 14* (SEPP 14) wetlands are also located immediately to the north of the Ash Dam toe drain and along the creeks to the north of the Ash Dam. Rural residential areas are located along the north western boundary of the Ash Dam and residential areas are located directly to the west and south of the Ash Dam.

Three existing groundwater monitoring wells installed to the north of the Ash Dam have been monitored on a quarterly basis since 2008 to assess seepage from the Ash Dam. A qualitative review of this data indicates that the groundwater is saline and slightly acidic and that measured concentrations of copper, lead, nickel and zinc consistently exceed the ANZECC (2000) trigger values for marine water quality. As a result, the EPA has requested additional groundwater investigations in this area and a Pollution Reduction Program (PRP) has been implemented under the Site EPL.

*AEC Methodology and Investigation Field Observations*

Intrusive soil and groundwater investigations within the active or rehabilitated areas of the Ash Dam were not considered necessary, as it is already acknowledged that these areas are impacted with waste materials (primarily ash). The investigations of this AEC therefore focused on identifying COPC that may have migrated from this AEC towards sensitive receptors.

A total of twenty-one soil bores were advanced and nineteen of these were converted into groundwater monitoring wells. Sampling locations were installed around the entire boundary of the Ash Dam, with the exception of an approximately 2 km stretch along the south western side of the Ash Dam, where the presence of a high pressure Jemena gas pipeline prevented the installation of sampling locations. The sampling locations within this AEC are presented on *Figures 6.2, 6.3 and 6.6 of Annex A*. Relevant borehole logs are presented within *Annex D*.

During the additional round of sampling undertaken on 27 May, 2014. Surface water from the toe drain was sampled. It was noted that this water was not flowing and appeared stagnant with orange staining. This sample was analysed for metals. The laboratory results are shown in *Table 5.0 in Annex B*.

During the sampling program, no staining or odours were noted on the Site surface. Visibly stressed vegetation was noted in the areas within approximately 30 m of the active portion of the Ash Dam, although it is noted that this could be related to a number of factors, potentially including inundation (refer to *Photograph 46 and 47 of Annex G*).

No staining was detected at any depth through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 5.9 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.16*.

**Table 5.16** *Field Observations Summary - AEC VO*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v -isobutylene equivalents)
VO_MW01	4	H <sub>2</sub> S odour at 3.2 m bgl	0- 8.7
VO_MW02	7	None	0-0.8
VO_MW03	7.5	H <sub>2</sub> S odour at 7 m bgl	0-5.9
VO_MW04	8	None	0
VO_MW05	10	None	0
VO_MW06	2.5	Shale staining	0
VO_MW07	10	None	0
VO_MW08	12.5	None	0
VO_MW09	12	None	0-2.4
VO_MW10	12	None	0-0.6

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v -isobutylene equivalents)
VO_MW11	12	None	0-3.4
VO_MW12	3	None	0
VO_MW13	5.1	None	0
VO_MW14	6	None	0
VO_MW15	5.5	None	0-0.5
VO_MW16	4.6	Possible ash	0-0.2
VO_MW17	4.5	None	0-1.2
VO_MW18	7	None	0-1.0
VO_MW19	5	None	0
VO_MW20	11	None	0-1.7
VO_SB01	3	None	0
VO_SB03	3	None	0-0.1

Groundwater field parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*. Electrical conductivity measurements indicated that the groundwater within this AEC ranged from fresh to highly saline conditions. The pH measurements in groundwater within this AEC were typically slightly acidic with a range from pH of 3.6 to 6.55. pH values of less than 4 were recorded in monitoring wells VO\_MW04, VO\_MW06, VO\_MW12, VO\_MW18 and VO\_MW19, which may indicate the presence of ASS conditions. VO\_MW04 is located near the Ash Dam toe drain, VO\_MW06 is located on the north western boundary of the Ash Dam and VO\_MW12 is located near the discharge point for the Ash Dam into Wye Creek. VO\_MW18 and VO\_MW19 are located immediately to the east of the Ash Dam.

No indications of contamination, such as sheen or odours, were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3 of Annex B*.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.0 of Annex B*.

The concentrations of TRH (C10-C16 excluding naphthalene) measured in soil samples collected from VO\_MW06 and VO\_MW10 at a depth of 0.2m bgl exceeded the ecological screening values for areas of ecological significance, but not the screening values for commercial industrial areas.

The nickel and zinc concentrations in selected soil samples marginally exceeded the ecological screening value for areas of ecological significance.

Asbestos was not reported in soil within this AEC.

*Groundwater Analytical Data*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.0 of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*

With the exception of metals, all COPCs were measured at concentrations below the laboratory LOR.

*Surface Water Analytical Results*

The surface water samples collected from within the Ash Dam toe drain reported concentrations of manganese greater than the adopted human health (drinking water) screening values and cobalt and zinc concentrations greater than the adopted ecological screening levels.

A comparison between the metal concentrations measured in the toe drain and those measured in the groundwater monitoring wells located immediately upgradient of the toe drain (including VO\_MW02, VO\_MW03 and VO\_X\_MW03) indicated that the manganese concentration in the toe drain were lower by a factor between 3 and 7 and the cobalt concentrations were lower by a factor of between 14 and 19. The zinc concentrations measured in the toe drain were of a similar order of magnitude to those measured in the immediately upgradient groundwater monitoring wells. Arsenic, nickel and selenium were measured at concentrations in excess of the adopted screening values in groundwater monitoring wells located immediately upgradient of the toe drain but not within the toe drain.

*Discussion*

The concentrations of TRH (C<sub>10</sub>-C<sub>16</sub> excluding naphthalene), benzo(a)pyrene, nickel and zinc measured in individual soil samples exceeded the ecological screening values adopted for areas of ecological significance, but not the screening values for commercial industrial areas. These results indicate that concentrations of TRH, PAH, nickel and zinc in soil around the boundary of the Ash Dam may be sufficient in some areas to adversely impact upon sensitive terrestrial organisms.

Overall however, a significant adverse effect on the terrestrial environment is not predicted on the basis of these results, particularly given the operational nature of the Ash Dam and the licensed placement of a variety of waste materials, including ash, within this structure.

Groundwater from monitoring wells within this AEC reported metals concentrations greater than the adopted human health and ecological screening values.

A consolidated discussion of this issue is presented in *Section 5.4*, but the surface water samples collected from within the Ash Dam toe drain indicate that lower concentrations are discharging into the downgradient area or that the surface water has been diluted by other inputs, such as rainfall.

### 5.3.16 *VP – Asbestos Landfills*

#### *Background*

There are six Asbestos Landfills located within the catchment of the Ash Dam. These Asbestos Landfills (referred to as “Dumps”) were closed in approximately 1995. Four of the Dumps (Dumps 1-4) have been closed and covered, revegetated and surveyed. Dump 5 is located entirely within the active area of the Ash Dam. Dump 6 is located predominantly within the active area of the Ash Dam, with a small portion located in bushland to the east of the active portion of the Ash Dam. Dump 4 is located within the previously active area of the Ash Dam which was rehabilitated around 2007. The Asbestos Landfills are fenced with signs to indicate the presence of asbestos contaminated wastes.

Detailed information about the waste materials disposed within the Asbestos Landfills was not available for review as a part of this assessment but it is understood that the primary material disposed within these areas was asbestos. The waste materials contained within the landfill areas have the potential to impact the conditions of underlying soil and groundwater.

Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions around the known delineated extent of the landfills.

#### *AEC Methodology and Investigation Field Observations*

Intrusive soil and groundwater investigations within the asbestos landfills were not considered safe or necessary, as it is already acknowledged that these areas are impacted with waste materials. The investigation locations in this AEC were distributed to target the soil and groundwater conditions around the perimeter of the known delineated extent of the landfills, as marked by the security fencing and signage and indicated in plans provided by Delta. The investigations within this AEC focussed on identifying COPCs that may have migrated from this AEC towards sensitive receptors.

A total of twelve soil bores were advanced around the perimeter of the known asbestos landfill areas. Two of these bores were converted to monitoring wells in the area downgradient of the three landfills located to the north of the Ash Dam (Dump 1, Dump 2 and Dump 3).

The installation of monitoring wells in the areas downgradient of the asbestos landfills was limited due to the rough terrain in this area, however the monitoring wells from the adjacent Ash Dam AEC (AEC VO) as well as surface water samples from AEC VR have also been considered. The three landfills known as Dump 4, Dump 5 and Dump 6 are located either within the area currently covered by the active Ash Dam or the rehabilitated part of the Ash Dam. The groundwater in these areas has been considered in the assessment of groundwater conditions in the Ash Dam AEC (AEC VO).

The sampling locations within this AEC are presented on *Figures 6.2 and 6.3 of Annex A*. Relevant borehole logs are presented within *Annex D*.

As anticipated, ash as well as coal and shale fragments were encountered at several locations in this AEC. Ash was identified from a depth of approximately 0.5 m bgl in the profiles of the three soil bores (VP\_SB09 and SP\_SB10) around the perimeter of the former "Dump 4", and a thin layer of ash was also encountered between 1.1 and 1.3 m bgl at VP\_SB07. All three of these soil bores are located within the rehabilitated ash disposal area. Coal and shale fragments were encountered within the surface soils at three locations, VP\_MW02, VP\_SB01 and VP\_SB02 which are located adjacent to the coal conveyor. There were no further staining or unusual odours detected at any depth through the sampled soil profile in this AEC. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 0.8 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.17*.

**Table 5.17** *Field Observations Summary - AEC VP*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v - isobutylene equivalents)
VP_MW01	9	None	0
VP_MW02	7	None	0-0.1
VP_SB01	1.5	Coal and shale present.	0-0.3
VP_SB02	1.5	Coal and shale present.	0-0.1
VP_SB03	1.5	None	0
VP_SB04	2.1	None	0
VP_SB05	3	Ash	0-0.2
VP_SB06	3	None	0-0.6
VP_SB07	3	Ash	0-0.5
VP_SB08	3	None	0-0.8
VP_SB09	1.5	Ash	0
VP_SB10	0.5	Ash	0

*Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.p of Annex B*.

The majority of measured concentrations of COPC were below the corresponding laboratory LOR, with the exception of TRH, PAH and metals. Measured concentrations of TRH and PAH constituents were detected in soil samples collected from VP\_SB02, however the measured concentrations did not exceed the adopted human health or ecological screening values.

Concentrations of various heavy metals were identified above the corresponding laboratory LOR in a number of soil samples collected from within this AEC. However all concentrations were below the adopted screening values with the exception of copper and zinc. The measured concentrations of copper and zinc in the soil sample collected from VP\_SB01 at a depth of 0.2 m bgl exceeded the adopted ecological screening values.

Asbestos was detected in two soil samples collected from within this AEC at VP\_MW02 at a depth of 2 m bgl and VP\_SB02 at a depth of 0.2 m bgl. In both soil samples there were no visual indicators of potential ACM during the sample collection in the field. In the soil sample collected from VP\_SB02 at a depth of 0.2 m bgl, the laboratory identified "several pieces of friable asbestos cement sheeting approximately 5 x 4 x 4 mm plus several loose bundles of friable asbestos fibres approximately 2 x 1 x 0.5 mm". The laboratory reported that amosite, crocidolite and chrysotile asbestos were present in the soil sample.

The asbestos quantification results reported that fibrous asbestos was detected at 0.034 % w/w and that asbestos fines and fibrous asbestos (<7 mm) were detected at 0.009 % w/w which is above the adopted human health screening criteria. In the soil sample collected from VP\_MW02 at a depth of 2 m bgl the laboratory identified "several pieces of friable asbestos cement sheeting approximately 4 x 3 x 2 mm plus several loose bundles of friable asbestos and unidentified mineral fibres approximately 2 x 1 x 0.5 mm". The laboratory reported that amosite and crocidolite asbestos were present in the soil sample. The asbestos quantification results reported that fibrous asbestos was detected at 0.117 % w/w and that asbestos fines and fibrous asbestos (<7mm) were detected at 0.035 % w/w which is above the human health screening criteria.

*Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.p of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of the majority of the COPCs were below the adopted screening values in the groundwater samples collected from within this AEC.

Benzene was detected at a concentration that marginally exceeded the adopted human health (drinking water) screening values in a single groundwater sample collected from VP\_MW01. This well was re-sampled eight weeks later and again benzene was detected at a concentration exceeding the adopted human health (drinking water) screening values. Copper and zinc were also detected at concentrations marginally exceeded the adopted ecological screening values in a groundwater sample VP\_MW02.

#### *Discussion*

The copper and zinc concentrations in the shallow soil sample collected from VP\_SB01 exceeded the adopted ecological screening values. These results may suggest a hotspot of metal impact in the vicinity of the asbestos landfill. The absence of elevated metal concentrations in other soil samples collected from within this AEC however, suggests that metal impacts are unlikely to be widespread in the areas surrounding the asbestos landfills. Concentrations of copper and zinc in excess of the ecological screening levels were identified in groundwater collected from this AEC. However the measured concentrations were consistent with those measured in monitoring wells up-gradient of the landfills in AEC VJ and VK.

The measured concentrations of benzene exceeded the adopted human health (drinking water) screening values in groundwater when sampled on two occasions. The monitoring well (VP\_MW01) is located downgradient of an asbestos landfill area. In the absence of potable groundwater use in this area, this exceedance is not considered representative of a significant potential risk to human health however may be indicative of a benzene source within the asbestos landfill. It is noted that the adopted recreational screening levels were not exceeded on either of the two sampling events.

Groundwater from monitoring wells within this AEC reported copper and zinc concentrations greater than the adopted ecological screening values. As metals have been identified at concentrations exceeding the adopted screening criteria in groundwater within all AECs a consolidated discussion of this issue is presented in *Section 5.4*.

### **5.3.17**

#### ***VQ - Dust Line***

##### *Background*

The Dust Line is an aboveground pipeline which transfers dust from the operational area of the Site to the Ash Dam. The asbestos register for the Site indicates that the dust pipes are constructed of asbestos containing materials (ACM).

Site personnel indicated that the pipe had been treated with paint to minimise the release of ACM to the environment. Investigations were undertaken to assess whether soil in the vicinity of the pipeline has been impacted by asbestos fibres, from the degradation of this equipment.

*AEC Methodology and Investigation Field Observations*

Twelve surface soil samples were collected from immediately beneath the Dust Line along the accessible aboveground section which is approximately 1.2 km in length. The sampling density is approximately 1 sample per 100 m along the targeted length of the pipework. A grid based inspection, in accordance with Western Australian (WA) Department of Health (DOH) (2009) *Guidance for the Assessment, Remediation and Management of Asbestos-Contaminated Sites*, could not be achieved due to the physical presence of piping (including asbestos) within the immediate vicinity.

Groundwater in this AEC was considered as part of adjacent AECs, and there were no monitoring wells targeted to this AEC. The sampling locations within this AEC are presented on *Figure 6.5 of Annex A*. Relevant borehole logs are presented within *Annex D*.

No field indicators of contamination, such as staining or odours were noted within this AEC. No staining or unusual odours were detected at any depth through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 0 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.18*.

**Table 5.18** *Field Observations Summary - AEC VQ*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v -isobutylene equivalents)
VQ_SB01	0.2	None	0
VQ_SB02	0.2	None	0
VQ_SB03	0.2	None	0
VQ_SB04	0.2	None	0
VQ_SB05	0.2	None	0
VQ_SB06	0.2	None	0
VQ_SB07	0.2	None	0
VQ_SB08	0.2	None	0
VQ_SB09	0.2	None	0
VQ_SB10	0.2	None	0
VQ_SB11	0.2	None	0
VQ_SB12	0.2	None	0

*Soil Analytical Results and Discussion*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 6 of Annex B*.

Fibrous asbestos detected in three soil samples from this AEC (VQ\_SB06\_0.1, VQ\_SB11\_0.2, VQ\_SB12\_0.2). However, the measured concentrations of asbestos fines and fibrous asbestos (%w/w) did not exceed the adopted human health screening value.

Fibrous chrysotile asbestos was detected in a soil sample from VQ\_SB06 at a depth of 0.1 m bgl and the laboratory report identified “several loose bundles of friable asbestos fibres approximately 2 x 1 x 0.5 mm”. Fibrous chrysotile and amosite asbestos was detected in a soil sample from VQ\_SB11 at a depth of 0.2 m bgl and the laboratory report identified “several loose bundles of friable asbestos fibres approximately 2 x 1 x 0.5 mm”. Amosite asbestos was detected in a soil sample from VQ\_SB12 at a depth of 0.2 m bgl and the laboratory report identified “two loose bundles of friable asbestos fibres approximately 3 x 1 x 0.5 mm”.

It is noted that this asbestos assessment is considered indicative in nature, and additional analysis, in accordance with ASC NEPM (2013) would need to be undertaken to comprehensively delineate asbestos impacts associated with this pipework. Given the presence of asbestos in the matrix of the pipeline materials, appropriate ongoing Workplace Health and Safety (WHS) management should be maintained.

### 5.3.18 *VR – Sediments in Surrounding Waterways*

#### *Background*

The Site is located in the Lake Macquarie catchment area, with Lake Macquarie identified as the main local hydrological feature. There are four Licensed Discharge Points (LDPs) for water from the Power Station under Environmental Protection License (EPL) 761, including;

- LDP 1 - Cooling Water outlet to Wyee Bay;
- LDP 2 - Discharges to the cooling water outlet from the ash water recycle system;
- LDP 4 - Release of seepage from Ash Dam rehabilitated area at the v-notch weir located at the toe of the Dam; and
- LDP 18 - Over boarding of the Ash Dam into the Wyee Creek diversion channel and Wyee Creek.

All B Station drains are also ultimately discharged via the Chain Valley Retention Basin A ('Lake Rodham') to Chain Valley Bay.

Lake Macquarie sediments and surface water have been identified as a potential AEC due to the discharges that these waterways receive from the Power Station, which include:

- cooling water that has passed through the plant and therefore:
  - has been treated with biocides and anti-scale chemicals;
  - is heated;
  - may contain traces of oil;
  - has potentially elevated salts and metals due to concentration created by evaporation.
- treated effluent from the oil-water separator associated with the operational site drainage network;
- overflow and potential seepage from the Ash Dam and associated tributary streams;
- stormwater runoff from across the Site; and
- groundwater from across the Site.

Surface water samples are collected from Lake Macquarie on a regular basis, as a part of the EPL conditions associated with the operation of the Site but the parameters analysed generally have not included metals (Delta Electricity, 2014). Discharges to Wyee Creek are also monitored when they exceed 2 hours in duration. These monitoring events identified exceedances of the ANZECC (2000) trigger values for marine water for metals and concentrations of selenium in excess of the ANZECC (2000) low reliability trigger value for marine water.

While some environmental assessment has been undertaken in this area, it is not considered that suitable characterisation of environmental conditions has been established. Given the absence of sufficient previous detailed environmental characterisation work at the Site, the numerous discharge points and sources of potential contaminants, further investigation was considered to be required to provide a baseline assessment of sediment and surface water conditions in this AEC.

This investigation focused on Chain Valley Bay, Mannering Bay, Wyee Bay, and Wyee Creek. Chain Valley Bay is located immediately to the north east of the Site. Mannering Bay, with Wyee Bay immediately beyond, is located to the north of the Site. Wyee Creek and the Wyee Creek diversion channel are located along the north western site boundary and function as part of the Ash Dam overflow system.

Recreational fishing and boating activities are undertaken in Lake Macquarie. Chain Valley Bay Reserve is located 1 km south of the operational area. This reserve is publically accessible, however it was noted during these investigation works that public use of this area appeared to be infrequent. Further to this, the reserve is heavily vegetated in most areas, with small clearings available for public use and few amenities which would suggest that the reserve is not frequently used.

The *Delta Coast Land Management Plan* (GHD, 2012) identified a number of sensitive aquatic environments within the Site buffer zones and adjacent areas. *State Environmental Planning Policy No. 14* (SEPP 14) wetlands are located in the vicinity of the Site; immediately to the north of the Ash Dam toe drain around the fringes of Mannering Bay, on the northern edge of Mannering Bay and along the waterways within the northern buffer zones.

During the additional round of sampling undertaken on 27 May 2014, surface water from the toe drain was sampled. It was noted that this water was not flowing and appeared stagnant with orange staining. This sample was analysed for metals. The laboratory results are shown in Table 5o, as the toe drain is located in Ash Dam AEC (VO).

#### *AEC Methodology and Investigation Field Observations*

Sediment and surface water were collected from 23 sampling locations. Sampling locations were distributed around the AEC as illustrated in *Figures 6.2 and 6.4 of Annex A*.

The field notes recorded during the sediment and surface water sampling activities are presented in *Annex E*. Logs of the sediment cores are presented in *Annex D*. A summary of the field parameters recorded during the surface water sampling is presented in *Table 3 of Annex B*.

The sediment collected in Wyee Creek and Mannering Bay were typically silty or sandy clay, with the exception of sample VR\_M\_SS05 where the top 50 cm was reported to comprise silty sand and gravelly sand. Sediments in Chain Valley Bay and Wyee Bay comprised of silt.

No field indicators of contamination, such as staining, sheen, or odours were noted within this AEC.

*Sediment Analytical Results*

The sediment analytical results compared to the adopted screening values are presented in *Table 4.r of Annex B*.

Measured concentrations of Total Recoverable Hydrocarbons were detected above the LOR in a number of individual samples collected from within Wyee Creek and Wyee Bay, however the measured concentrations did not exceed the adopted screening values. Measured concentrations of BTEX in sediment samples analysed were also below the corresponding laboratory LORs.

Phenols were detected at concentrations marginally above the laboratory LORs in two of the sediment samples collected from within Wyee Creek. Screening criteria for the individual phenols detected were not available, but the total concentration of phenols measured in the samples did not exceed the RIVM (2001) ecological serious risk concentration for phenol.

Polycyclic Aromatic Hydrocarbons were detected at concentrations marginally above the corresponding laboratory LORs but below the adopted screening values in a number of individual samples collected from across the AEC. Exceedances of the ISQG-low values for acenaphthene, anthracene, naphthalene, fluorene and/or phenanthrene were recorded in all of the samples collected from within Wyee Bay. Total PAHs only marginally exceeded the ISQG-Low value of 4 mg/kg in the sediment samples collected from depths up to 0.2 m below the sediment surface at VR\_W\_SS02 (5.38 mg/kg) and VR\_W\_SS03 (5.05 mg/kg), which are located in the central portion of Wyee Bay, in close proximity to the mouth of Mannering Bay. The source of these PAH impacts has not been identified, but could potentially include inputs from the Power Station or a range of external sources, such as recreational boating or mining within surrounding areas.

Measured TOC values in Wyee Bay were reported between 5.23% and 15.6%. ANZECC (2000) recommends normalizing the ISQG values to TOC to account for the reductions in bioavailability that can be associated with the presence of organic matter in sediment. Following the normalisation of the measured PAH concentrations to 1% TOC, the resultant values did not exceed the adopted screening values.

Metal concentrations in sediment were generally below the adopted screening values. Cadmium was identified in individual samples collected from within Wyee Creek, the control area and Wyee Bay at concentrations marginally in excess of the ISQG-low value. Two sediment samples collected from within Wyee Bay also returned copper concentrations marginally in excess of the ISQG-low values.

In the absence of ANZECC/ARMCANZ (2000) ISQG values for selenium, the sediment results were compared against the British Columbia (2001) sediment guideline for selenium in marine sediment 2 mg/kg. Exceedances of this screening value were identified in numerous samples collected from within the lower reaches of Wyee Creek and within Mannering Bay. A single sample from the control area also demonstrated a selenium concentration of 4 mg/kg.

The maximum selenium concentration reported in Wyee Creek was 26 mg/kg, with this result recorded at VR\_C\_SS02, located in the portion of the creek that flows along the northern edge of Mannering Bay. The selenium concentrations measured in sediment samples collected from within Wyee Creek generally increased along the Creek towards Mannering Bay. The most elevated selenium results within the Wyee Creek sediment were generally recorded in the surface samples.

Relatively consistent concentrations of selenium were recorded throughout Mannering Bay, with between 4 and 8 mg/kg reported in the surface samples and between < 1 mg/kg and 6 mg/kg reported in the deeper samples.

#### *Surface Water Analytical Results*

The surface water analytical results were compared to the adopted ecological and human health (recreational) screening values, as presented in *Table 5.r* of *Annex B*.

The measured concentrations of phenols, BTEX, TRH and PAH were less than the corresponding laboratory LORs and the adopted screening values in all of the surface water samples analysed.

Zinc and copper concentrations exceeded the adopted ecological screening values in approximately 60% the surface water samples. The copper exceedances were generally marginal, at less than twice the adopted screening values whereas the zinc concentrations were up to approximately 4.5 times the screening value.

Three marginal exceedances of the cobalt screening values were recorded in surface water samples collected from within Wyee Creek. The metal concentrations did not exceed the adopted human health (recreational) guidelines in any of the surface water samples.

#### *Discussion*

##### Sediment

As noted in Simpson *et al.* (2005), the ISQG-low values represent concentrations below which the frequency of adverse biological effects is expected to be very low, while the ISQG-high represents concentrations above which adverse biological effects are expected to occur more frequently.

If a detected concentration exceeds the relevant ISQG, it does not necessarily mean that adverse biological effects will occur, but rather that more detailed consideration of the results may be required.

Cadmium was identified in individual samples collected from within Wyee Creek, the control area and Wyee Bay at concentrations marginally in excess of the ISQG-low value. Two sediment samples collected from within Wyee Bay also returned copper concentrations marginally in excess of the ISQG-low values. The distribution of these impacts is not suggestive of significant cadmium and cobalt impacts in Lake Macquarie sediments as a result of the operation of the Vales Point Power Station.

Selenium enrichment in sediment has previously been assessed in Lake Macquarie and has been attributed to atmospheric deposition from the power stations, dispersion of dissolved or particulate-bound selenium from fly ash, urban runoff and sewage (Kirby *et al.*, 2001). Selenium concentrations as high as 17.2 mg/kg were reported in Mannering Bay in a published scientific report (Peters *et al.*, 1999). Exceedances of the selenium screening value were identified in numerous samples collected from within the lower reaches of Wyee Creek and within Mannering Bay. The maximum selenium concentration reported in Wyee Creek was 26 mg/kg, with the selenium concentrations measured in sediment samples collected from within Wyee Creek generally increasing along the Creek towards Mannering Bay. Relatively consistent concentrations of selenium were recorded throughout Mannering Bay, at up to 8 mg/kg.

It is considered likely that discharges from the Ash Dam, potentially including licensed discharges, runoff and groundwater flow have contributed to the selenium impacts identified in Wyee Creek and Mannering Bay. Other potential sources within the catchment include mines, other power stations and other industries. The selenium concentrations identified in the current assessment were of the same order of magnitude as those identified in historic investigations (e.g. Peters *et al.*, 1999), suggesting that the selenium load in Wyee Creek and Mannering Bay sediments have not increased significantly in recent years.

#### Surface Water

Overall, the surface water results do not suggest that there has been significant impact on surface water quality within Wyee Creek, Mannering Bay, Wyee Bay, or Chain Valley Bay as a result of inputs from the Site.

Copper and cobalt concentrations marginally exceeded the adopted ecological screening values were identified in a number of samples, but a clear link between these samples and the Site was not apparent in the data. Zinc concentrations exceeded the adopted ecological screening values in approximately 60% the surface water samples, suggesting that background conditions may contribute to these concentrations.

The samples collected from the upper reaches of Wyee Creek generally demonstrated the highest zinc concentrations, which may reflect a contribution from the Ash Dam but which may also reflect the fact that these samples were collected in a riparian rather than estuarine environment and as such are more likely to be influenced by factor such as runoff and erosion.

### 5.3.19 VS - TransGrid Switchyard

#### *Background*

The TransGrid Switchyard is located on the western side of the cooling water canal, adjacent to the chlorine plant, hydrogen plant and Site canteen. The Vales Point Fire Training Area is located adjacent to the TransGrid Switchyard to the south east. The Switchyard is fenced and largely covered with hardstanding. The TransGrid Switchyard is not owned or operated by Delta Electricity. The COPC within the switchyard are related to the current use and storage of transformer oil and historically the transformer oil may have contained PCBs. The investigations within this AEC included the non-operational lands outside the TransGrid Switchyard and were distributed around the perimeter the target migration of potential contaminants from this AEC towards sensitive receptors.

No soil or groundwater investigations are known to have been completed within this AEC to date. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

#### *AEC Methodology and Investigation Field Observations*

A total of six soil investigation bores, five of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater. The investigations within this AEC included the non-operational lands outside the TransGrid Switchyard and were distributed around the perimeter the target migration of potential contaminants from this AEC towards sensitive receptors.

Data collected from this AEC has also been used to evaluate the presence of COPCs in soils and groundwater that may be associated with the Vales Point Fire Training Area.

No field indicators of contamination, such as staining or odours were noted within this AEC. No staining or unusual odours were detected at any depth through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 8.8 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.19*.

**Table 5.19** *Field Observations Summary – AEC VS*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v -isobutylene equivalents)
VS_MW01	5	None	0-0.8
VS_MW02	6.0	None	0-1.4
VS_MW03	6.3	None	0.1-0.9
VS_MW04	5.0	None	0- 0.3
VS_MW05	5.0	None	0.1-8.8
VS_SB01	3.0	None	0-0.2

Groundwater parameters recorded during the groundwater sampling works are presented in *Table 3 of Annex B*. Field parameters indicated brackish and slightly acidic groundwater conditions.

No indications of contamination, such as sheen or odours, were observed during groundwater sampling within this AEC. A summary of field observations from the groundwater sampling works are presented within *Table 3 of Annex B*.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.s of Annex B*.

Measured concentrations of COPCs were below the adopted screening values in the soil samples collected from within this AEC. The majority of measured concentrations were also below or close to the corresponding laboratory LOR.

Measured concentrations of various heavy metals were above the corresponding laboratory LOR in a number of soil samples collected from within this AEC. However, all concentrations of heavy metals in soils within this AEC were below the adopted screening values.

Asbestos was not detected in any of the soil samples analysed from this AEC.

#### *Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.s of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*

Measured concentrations of the majority of the COPCs were below the laboratory LOR and adopted ecological and human health screening values in all groundwater samples analysed, with the exception of metals in groundwater.

*Discussion*

No exceedances of the adopted screening values were identified in soil samples collected from within this AEC.

Groundwater from monitoring wells within this AEC reported metal concentrations greater than the adopted ecological screening values and a consolidated discussion of this issue is presented in *Section 5.4*.

**5.3.20 VT - Fly Ash Plant***Background*

The Fly Ash Plant is located immediately adjacent to the Power Station for the purpose of reusing the fly ash that is produced as a by-product of generating power. The majority of this AEC is covered in hardstanding and comprises a truck turning circle. Also located within this AEC are a weigh bridge and overhead silos.

It is understood that the Plant is not operated by Delta and that fly ash is transferred directly from the Power Station into the overhead silos located above a weighbridge. Trucks are then filled from overhead while stationed on the weighbridge. The fly ash is then trucked from the Site.

The Fly Ash Plant is a potential AEC due to the storage and handling of ash within the area and heavy vehicle traffic passing through the area. No soil or groundwater investigations are known to have been completed within this AEC to date. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

*AEC Methodology and Investigation Field Observations*

A total of three soil investigation bores, two of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater. The sampling locations within this AEC are presented on *Figure 6.5* of *Annex A*. Relevant borehole logs are presented within *Annex D*.

No field indicators of contamination, such as staining or odours were noted within this AEC. No staining or unusual odours were detected at any depth through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 1.9 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.20*.

**Table 5.20** *Field Observations Summary – AEC VT*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v -isobutylene equivalents)
VT_MW01	7.5	None	0-1.0
VT_MW03A	1.5	None	0-0
VT_MW03B	7.0	None	0-1.9

Groundwater samples were collected from the two groundwater monitoring wells present within the AEC. Groundwater parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*. Field parameters indicated fresh to brackish groundwater conditions and pH values of 4.1 were recorded in both monitoring wells indicating slightly acidic groundwater conditions.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.t of Annex B*.

The majority of measured concentrations of COPCs were also below or close to the corresponding laboratory LOR.

Measured concentrations of various heavy metals were reported above the corresponding laboratory LOR in a number of soil samples collected from within this AEC. All concentrations were however below the adopted screening values, with the exception of copper and zinc in the soil sample collected from VT\_MW01 at 0.2 m bgl which exceeded the adopted ecological screening values for commercial/industrial sites.

Asbestos was not detected in any of the soil samples collected from within this AEC.

#### *Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.t of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

With the exception of metals, the measured concentrations of the COPCs were below the adopted screening values in all groundwater samples analysed from within this AEC.

#### *Discussion*

Exceedances of the adopted screening values for zinc and copper were identified in a shallow soil samples collected from within this AEC.

Given the operational nature of this AEC and the fact that it is fenced and primarily covered in hardstanding, these exceedances are not considered to represent a significant risk to the environment under the ongoing use of the Site as a Power Station.

Groundwater from monitoring wells within this AEC reported metal concentrations greater than the adopted ecological screening values and a consolidated discussion of this issue is presented in *Section 5.4*.

### 5.3.21 *VU - Buffer Lands and Boundaries*

#### *Background*

Much of the area surrounding the operational areas of the Site and the Ash Dam is a buffer zone. Land within this AEC is largely undeveloped and is currently dominated by bushland and decommissioned and operational coal mines. The *Delta Coast Land Management Manual* (GHD, 2012) indicates that threatened flora and fauna has been identified in the buffer lands surrounding the Ash Dam and Wyee Rail Coal Unloader.

No soil or groundwater investigations are known to have been completed within this AEC to date. Given the absence of previous environmental characterisation work, further investigation was considered to be required to provide a baseline assessment of soil and groundwater conditions in this area.

#### *AEC Methodology and Investigation Field Observations*

A total of twenty-two soil investigation bores, seventeen of which were completed as groundwater monitoring wells, were advanced within this AEC to assess potential impacts to soil and groundwater.

The sampling locations within this AEC are presented on *Figure 6.1 to 6.6* of *Annex A*. Relevant borehole logs are presented within *Annex D*.

Ash, shale and black staining were observed at VU\_MW18 at a depth of 0.8-0.9 m bgl. An organic odour was noted at VU\_MW19 at a depth of 0.4 to 0.65 m bgl and was associated with a sandy clay. The laboratory results did not indicate the presence of COPCs in soil above the screening values associated with the observed black staining or organic odour. No other field indicators of contamination, such as staining or odours were noted within this AEC. No further staining or unusual odours were detected at any depth through the sampled soil profile. Measured concentrations of ionisable volatile compounds via headspace analysis were noted not to exceed 1.9 ppm v (isobutylene equivalent) in any soil sample collected from this AEC.

A summary of the field observations from the drilling works are presented within *Table 5.21*.

**Table 5.21** *Field Observations Summary – AEC VU*

Borehole ID	Depth (m bgl)	Visual or Olfactory Evidence	PID Range (ppm v -isobutylene equivalents)
VU_MW01	3.9	None	0-1.9
VU_MW02	6.5	None	0-9.6
VU_MW03	12	None	0-3.9
VU_MW04	9	None	0-6.4
VU_MW05	9.5	None	0-2.8
VU_MW06	10	None	0-3.8
VU_MW07	8.7	None	0-2.2
VU_MW08	13.4	None	0-7.6
VU_MW09	15	None	0-2.3
VU_MW10	5.5	None	0-3.8
VU_MW11	0.1	None	0
VU_MW12	7	None	0-2.1
VU_MW13	11	None	0-3.3
VU_MW14	12	None	0-0.1
VU_MW15	6	None	0-0.1
VU_MW16	9.5	None	0-2.4
VU_MW17	7.5	None	0-1.9
VU_MW18	1.5	Black staining	0-0.2
VU_MW19	1.4	Organic odour	0-0.4
VU_MW20	13	None	0-1.6
VU_SB01	0.4	None	0-0.1
VU_SB02	1.5	None	0
VU_SB03	3	None	0-0.1

Groundwater parameter measurements collected during the groundwater sampling works are presented in *Table 3 of Annex B*. Electrical conductivity measurements indicated fresh to brackish groundwater conditions. Groundwater samples collected from VU\_MW02, VU\_MW15 and VU\_MW16 reported pH values of less than 4, which may be indicative of Acid Sulfate Soil (ASS) conditions. VU\_MW02 is located to the north east of the operational area adjacent to Lake Macquarie and VU\_MW15 is located to the north west of the TransGrid Switchyard (AEC VS). VU\_MW16 is located to the east of the Ash Dam. Field pH measurements recorded across the remainder of this AEC indicated acidic to neutral groundwater conditions.

#### *Soil Analytical Results*

The soil analytical results have been compared to the adopted human health and ecological screening values as presented in *Table 4.u of Annex B*.

Measured concentrations of COPCs were below the adopted human health screening values in all soil samples collected from within this AEC. Concentrations of TRH were reported above the laboratory LOR in two samples, VU\_MW20 at a depth of 0.5 m bgl and VU\_MW01 at a depth of 1.5 m bgl however the concentrations did not exceed the adopted human health screening values.

Measured concentrations of COPCs were below the adopted ecological screening values (commercial/industrial) in all soil samples collected from within this AEC. Concentrations of copper, nickel and zinc exceeded the adopted ecological screening values for areas of ecological significance in a number of soil samples collected across this AEC, including deep samples (> 2 m bgl) in VU\_MW17, VU\_MW04, VU\_MW14 and VU\_MW10 and shallow samples (< 2 m bgl) in VU\_MW01, VU\_MW03 and VU\_SB03. .

#### *Groundwater Analytical Results*

Groundwater analytical results compared to the adopted screening values are presented in *Table 5.u of Annex B*. Exceedances of the adopted screening values are also graphically presented in *Figure 9 of Annex A*.

Measured concentrations of the majority of the COPCs were below the laboratory LOR in all groundwater samples analysed. The exceptions to this were detections of various metals within groundwater across this AEC.

#### *Discussion*

No exceedances of the adopted human health screening values were identified in soil samples collected from within this AEC. Concentrations of copper, nickel and zinc exceeded the adopted ecological screening values for *areas of ecological significance* (as defined in ASC NEPC, 2013) in a number of deep soil samples (>2 m bgl) and shallow soil samples (<2 m bgl). However, the concentrations of copper, nickel and zinc in all soil samples analysed in this AEC were below the adopted ecological screening values for commercial/industrial sites.

The EILs apply principally to contaminants in the top 2 m (i.e. shallow soil samples) (ASC NEPC, 2013) and therefore the screening value exceedances identified in the deep samples are not considered to be representative of a significant potential risk to the terrestrial environment of these areas.

The shallow soil samples demonstrating exceedances of the ecological screening values for *areas of ecological significance* (VU\_MW01, VU\_MW03 and VU\_SB03) are located on the eastern side of the operational area. The *Delta Coast Land Management Manual* (GHD, 2012) did not identify threatened or endangered species in this area and hence the adoption of the screening values for the protection of *areas of ecological significance* is overly conservative for these samples. Therefore, on the basis that the measured concentrations did not exceed the ecological screening values for commercial/industrial areas, the measured metal concentrations are not considered to represent a significant potential risk to the environment under the ongoing use of the Site as a Power Station.

#### 5.4 METAL AND METALLOID CONCENTRATIONS IN GROUNDWATER

Metals and metalloids can occur naturally in groundwater, and an assessment of background conditions forms an integral part of the evaluation of metal and metalloid concentrations reported. This is especially relevant where potential off-site sources of metals and metalloids exist, including historical and current underground coal mining works which occur extensively in the area surrounding and underlying the majority of the Site, including the Ash Dam.

For the purposes of this assessment, the following monitoring wells have been put forward as background monitoring wells; VO\_MW09 to VO\_MW11 and VU\_MW17. These monitoring wells are located up-hydraulic gradient of all identified on-site sources. pH levels and ORP (two key controls on metal and metalloid solubility) in the aforementioned monitoring wells fell within the mid-range of measurements recorded across the monitoring well network at the Site, with pH measurements from the background monitoring wells varying between 3.8 to 5.7 and ORP between -82 mV and 318 mV (site-wide groundwater pH and ORP measurements varied between 3.3 and 6.8 and -259 mV and 500 mV respectively).

These monitoring wells were considered as the general background data points for the Site and are referred to as the *Background Monitoring Wells* in the remainder of the report.

The concentrations of metals in groundwater have been compared to the *Background Monitoring Wells* (as applicable), and for the purposes of this assessment, concentrations equalling or exceeding the maximum background concentrations by a factor of two were considered as potentially indicative of concentrations above background values. It is noted that a limited number of monitoring wells are available as background monitoring wells and that only one round of data is available for comparison of reported concentrations from these monitoring wells to the rest of the monitoring network established during the Stage 2 ESA.

The evaluation of metal(loid) concentrations in relation to background conditions based on the approach outlined here should therefore be seen as a preliminary review of background conditions given the relatively limited nature of the background dataset. While the background dataset is limited, the approach does allow for the preliminary identification of potential background conditions.

Note that all the metal and metalloid (including arsenic and selenium) concentrations described below are for field filtered samples (filtered with single-use 0.45 µm filters), with concentration ranges and averages based on primary samples only.

*Arsenic*

Arsenic concentrations ranged from the LOR of <1 µg/L to 184 µg/L with an average concentration of 5.5 µg/L across the monitoring well network. Concentrations equalling or exceeding the lowest adopted screening value of 10 µg/L (drinking water criteria) were limited to 12 of the 117 monitoring wells sampled. Samples with exceedances of the adopted screening values were taken from one monitoring well located at the vehicle refuelling depot, and a number of monitoring wells located downgradient of the ash dam.

In the *Background Monitoring Wells* arsenic concentrations averaged 1 µg/L with a maximum reported concentration of 3 µg/L. Background concentrations were below the assessment criteria and the elevated arsenic concentrations are therefore not considered attributable to background concentrations.

*Cobalt*

Cobalt concentrations ranged from the LOR of 0.9 µg/L to 169 µg/L with an average concentration of 19 µg/L across the groundwater monitoring well network. Concentrations equalling or exceeding the lowest adopted screening values of 1 µg/L (marine adopted ecological screening values) were reported for 58 of the 64 monitoring wells sampled for cobalt.

Samples with exceedances of the adopted screening values were taken from monitoring wells spread across the Site, including the former A Station power block, the water treatment plant, transformer area, vehicle refuelling area, waste oil storage area, Wyee rail coal unloader area, coal storage area and ash dam.

Cobalt concentrations In the *Background Monitoring Wells* averaged 35 µg/L with a maximum reported concentration of 43 µg/L. Reported concentrations a factor of two above the maximum reported background concentration were limited to two monitoring wells (VO\_MW04 and VO\_MW06) located downgradient of the ash dam and one monitoring well (VJ\_MW09) located at the coal storage area. Reported concentrations above what can be considered as the background levels are therefore highly localised to either the coal storage area or the ash dam compared to the number of samples exceeding the adopted assessment values.

*Copper*

Copper concentrations ranged from the LOR of <0.5 µg/L to 596 µg/L across the groundwater monitoring well network, with an average concentration of 13 µg/L. Concentrations equalling or exceeding the lowest adopted screening values of 1.3 µg/L (marine adopted ecological screening values) were recorded in samples from 91 of the 117 monitoring wells sampled.

Samples reporting exceedances of the adopted screening values for copper were collected from monitoring wells spread across the Site, including the former A Station and B Station power blocks, the transformer area, vehicle refuelling area, waste oil storage area, Wyee rail coal unloader, coal storage area, sewage treatment plant and Ash Dam.

Copper concentrations in *Background Monitoring Wells* averaged 7 µg/L with a maximum reported concentration of 18 µg/L. Reported concentrations a factor of two above the maximum reported background concentration were limited to a total of eight monitoring wells located at the vehicle refuelling depot, the fuel oil installation area and downgradient of the Ash Dam.

#### *Lead*

Lead concentrations ranged from the LOR of <1 µg/L to 231 µg/L across the groundwater monitoring well network, with an average concentration of 12 µg/L. Concentrations equalling or exceeding the lowest adopted screening values of 4.4 µg/L (marine adopted ecological screening values) were identified in samples from 35 of the 117 monitoring wells sampled. Monitoring wells with samples exceeding the adopted screening values were located predominantly in the vehicle refuelling area, mobile plant maintenance area, Wyee rail coal unloader and at the ash dam. Exceedances were however also noted at the former A Station power block, sewage treatment plant, contaminated wastewater treatment system and waste oil storage area.

In the *Background Monitoring Wells* lead concentrations averaged 7 µg/L with a maximum reported concentration of 20 µg/L. Reported concentrations a factor of two above the maximum reported background concentration were limited to a total of eight monitoring wells, located in the mobile plant maintenance area, the switchyard and downgradient of the ash dam.

#### *Manganese*

Manganese concentrations ranged from below the LOR of 11 µg/L to 17 300 µg/L across the groundwater monitoring well network, with an average concentration of 1287 µg/L. Concentrations exceeding the adopted screening values of 500 µg/L (drinking water criteria) were identified in samples from 23 of the 64 monitoring wells sampled. Samples with exceedances of the adopted screening values were taken from monitoring located in the Wyee rail coal unloader area, the mobile plant maintenance area, the coal storage area and ash dam.

Manganese concentrations in the *Background Monitoring Wells* averaged 1187 µg/L with a maximum reported concentration of 2290 µg/L.

Reported concentrations a factor of two above the maximum reported background concentration were limited to three monitoring wells; one monitoring well located at the mobile plant maintenance area (VK\_MW07), one monitoring well at the coal storage area (VJ\_MW09) and one monitoring well located downgradient of the ash dam (VO\_MW06).

#### *Nickel*

Nickel concentrations ranged from below the LOR of  $<0.5 \mu\text{g/L}$  to  $133 \mu\text{g/L}$  across the groundwater monitoring well network, with an average concentration of  $15 \mu\text{g/L}$ . Concentrations exceeding the lowest adopted screening value of  $20 \mu\text{g/L}$  (drinking water criteria) were identified in samples from 32 of the 117 monitoring wells sampled. Samples with exceedances of the adopted screening values were taken from monitoring wells spread across the Site, including the former A Station and B Station power blocks, the main store, vehicle refuelling area, mobile plant maintenance area, the coal storage area, chlorine plant and ash dam.

Nickel concentrations in the *Background Monitoring Wells* averaged  $14 \mu\text{g/L}$  with a maximum reported concentration of  $32 \mu\text{g/L}$ . Reported concentrations a factor of two above the maximum reported background concentration were limited to three monitoring wells located downgradient of the ash dam (VO\_MW04, VO\_MW06 and VO\_X\_MW02).

#### *Selenium*

Selenium concentrations ranged from below the LOR to  $276 \mu\text{g/L}$  across the groundwater monitoring well network, with an average concentration of  $16 \mu\text{g/L}$ . Concentrations exceeding the screening value of  $10 \mu\text{g/L}$  (drinking water criteria) were identified in samples from nine of the 63 monitoring wells sampled for selenium. Monitoring wells with samples that exceeded the adopted screening values were limited to one location (VK\_MW06) at the mobile plant maintenance area and eight monitoring wells at the ash dam.

Selenium concentrations in the *Background Monitoring Wells* were below the laboratory LOR (which varied between  $<0.1 \mu\text{g/L}$  to  $<10 \mu\text{g/L}$ ) with the highest reported concentration being  $10 \mu\text{g/L}$  (on a sample with a laboratory LOR of  $10 \mu\text{g/L}$ ). Reported concentrations measuring a factor of two above the maximum reported background concentration included samples taken from eight monitoring wells, all located downgradient of the ash dam.

*Zinc*

Zinc concentrations ranged from 6 µg/L to 1200 µg/L across the groundwater monitoring well network, with an average concentration of 63 µg/L. The majority of monitoring wells (108/117) exceeded the adopted screening values of 15 µg/L (marine adopted ecological screening values).

Zinc concentrations in the *Background Monitoring Wells* averaged 65 µg/L, with a maximum reported concentration of 116 µg/L. Reported concentrations measuring a factor of two above the maximum reported background concentration included samples taken from one monitoring well, VO\_MW04 located downgradient of the ash dam.

*Potential Influence of Acid Sulfate Soils*

Quaternary alluvial sediments that may contain sulfides liable to the creation of acid sulfate soil conditions when oxidised have been identified in locations near the marine environment, specifically in the vicinity of VO\_MW04 where a pH of 3.6 has been measured and discoloured water ponding typical of acid sulfate soil conditions observed.

The ash dam was built in the course of Mannering Creek and the ash dam deposits are therefore expected to be largely underlain by quaternary alluvial sediments. Disturbance of the sediments during construction of the ash dam, and/or infiltration of ash dam water (that would be expected to be largely oxygenated) into the underlying sediments, may have resulted in the creation of acid sulfate soil conditions with naturally occurring sediments contributing to the elevated metal concentrations observed in groundwater.

pH values of less than 4 were recorded in monitoring wells VO\_MW04, VO\_MW06, VO\_MW12, VO\_MW18 and VO\_MW19, which may indicate the presence of ASS conditions. VO\_MW04 is located near the Ash Dam toe drain, VO\_MW06 is located on the north western boundary of the Ash Dam and VO\_MW12 is located near the discharge point for the Ash Dam into Wyee Creek. VO\_MW18 and VO\_MW19 are located immediately to the east of the Ash Dam.

It is noted that relatively acidic groundwater conditions (with pH levels below 4.5) have been observed in a relatively large number of groundwater monitoring well locations across the Site, including a number of monitoring wells installed in the Munmorah Conglomerate and located away from the alluvial sediments (including background monitoring well VU\_MW17 with a pH of 3.8). Relatively acidic conditions are therefore not restricted to areas where disturbed alluvial sediments may be located, as a result of the construction of the ash dam.

*Summary*

Based on the preliminary assessment of background conditions outlined in this report, metal concentrations seen as indicative of background values were generally higher than the lowest adopted screening criteria. The majority of monitoring wells across the Site reported metal concentrations that did not exceed concentrations seen as indicative of background conditions. Specifically for cobalt, copper, nickel and zinc, the number of monitoring wells with samples that have concentrations above background values were generally an order of magnitude less than the number of monitoring wells with exceedances of the adopted assessment criteria (i.e. one tenth of the number of samples exceeding the adopted screening criteria). For lead and manganese, the number of samples with concentrations above background values was at least a factor of four less than the number of samples exceeding the adopted screening criteria.

Conversely, based on the approach to assessing background conditions as discussed above, the arsenic exceedances and the majority of selenium exceedances of the assessment criteria cannot be attributed to background conditions. Where concentrations of metal(loids) in groundwater were measured above background values, impact generally appears to be localised in distinct areas of the site with the main potential source areas being the vehicle refuelling depot, the coal storage area and the ash dam. The majority of samples with concentrations reported above the background values were taken from monitoring wells located downgradient of the ash dam.

Based on the assessment outlined in the report the ash dam appears to present a primary source of arsenic and selenium to groundwater. The data further indicates that the ash dam may act as a secondary source of cobalt, copper, lead, manganese, nickel, and zinc, contributing to metal concentrations that are generally elevated in background conditions.

If disturbed alluvial sediments underlie the ash dam, these sediments may be contributing to elevated metal(loid) concentrations with potential sulfide oxidation in sediments resulting in acid sulfate conditions. As historical and current underground coal mining works occur extensively in the area surrounding and underlying the majority of the Site (including the ash dam), the mine works and related subsidence effects (which could enlarge fracture surfaces within bedrock) may further have contributed to elevated metal(loid) concentrations observed in groundwater. The long term disposal of waste ash materials, which are known sources of metal contaminants, within the Ash Dam, may also have contributed to metal impacts in the underlying groundwater. The long term storage of coal materials within the Coal Storage Area may also have contributed to the observed metal impacts in groundwater in this area.

Acidic groundwater conditions in the vicinity of the Vehicle Refuelling Area appear to have contributed to the presence of elevated metal concentrations in groundwater, although it is noted that there are also areas of the Site where low pH conditions in groundwater have not resulted in metal concentrations in excess of background conditions.

## 5.5

### *DATA QUALITY*

The data presented in the ESA was considered to generally be of a suitable quality and completeness to provide a baseline of environmental conditions at the Site. Whilst some minor non-conformances have been identified in relation to field and laboratory QA/QC, these are not considered to have a material impact on the outcomes of this assessment. A detailed review of the Data Quality of this assessment is provided in *Annex F*.

Comparison of the laboratory Limit of Reporting (LOR) to the screening values has been undertaken, confirming that the screening values are less than the laboratory LOR, with the exception of the following compounds:

- Some volatile organic compounds in water (including vinyl chloride, chloromethane, bromomethane, 1,2-Dichloroethane, hexachlorobutadiene, 1,2,3-trichlorobenzene and 1,2-dibromomethane) and pentachlorophenol have LORs marginally above the adopted ecological protection criteria and/or above the drinking water guidelines. The assessment results do not suggest that these contaminants are key contaminants of concern.
- PAHs in water, including Benzo(a) pyrene and Carcinogenic PAHs (as BaP TEQ), have LORs above the drinking water and recreational guidelines. The LORs are within the same order of magnitude as the recreational screening value and an order of magnitude above the drinking water guideline. The assessment suggests that these contaminants are not key COPC, as PAH compounds in excess of the screening values have not been identified in groundwater in this assessment.
- TRH (>C10-C16 minus naphthalene) in soils have LORs above the adopted ESL for areas of ecological significance by a factor of 2. This threshold does not apply to soils across the whole site, only being applicable to areas of the Ash Dam (AEC VO) and Wyee Rail Coal Unloader (AEC VN).

Selenium in groundwater has an LOR above the adopted ecological screening value but above the adopted human health screening values. The LOR for selenium in surface water samples collected from within the inlet/outlet canal fell below the adopted ecological screening value and exceedances of the screening criteria were not observed in the surface water samples. On this basis, the LOR non-conformances for selenium in groundwater are not considered to represent a significant data gap in this assessment.

## 6 OVERALL DISCUSSION

The primary objective of this Stage 2 ESA was to develop a baseline assessment of environmental conditions at the Site and within the immediate surrounding receiving environments at or near the time of the transaction. The results of the assessment have also been used to assess:

- The nature and extent of soil and/or groundwater impact on / beneath the Site and in relation to neighbouring sensitive receptors.
- Whether the impacts at the Site represent a risk to human health and/or the environment, based on the continuation of the current use.
- Whether the impact at the Site is likely to warrant notification /regulation under the *CLM Act 1997*.
- Whether material remediation is considered likely to be required.
- Whether the data collected during the assessment was of a suitable quality and completeness to provide a baseline of environmental conditions at the Site.

The overall results of the assessment are discussed herein, with reference to these objectives.

### 6.1 SUMMARY – THE NATURE AND EXTENT OF SOIL, SEDIMENT, GROUNDWATER AND SURFACE WATER IMPACT

A CSM was developed and refined, which identified the following ecological and human receptors:

- indoor and outdoor human health receptors in the form of onsite and offsite workers;
- intrusive maintenance workers both on and offsite;
- offsite residential receptors, living in the vicinity of the operational area or Ash Dam;
- recreational users of Mannering Bay, Wyee Bay and Chain Valley Bay;
- recreational users of Tom Barney Oval;
- aquifers beneath the Site and nearby potable and stock watering wells; and
- ecological receptors, including those in the vegetated buffer lands and aquatic environments of Mannering Bay, Wyee Creek, Wyee Bay and Chain Valley Bay.

Soil, sediment, surface water and groundwater data were compared against published environmental quality levels to provide a screening level assessment of potential risks to these identified receptors. The findings of the screening process indicated that concentrations in soil, sediment, surface water and groundwater generally complied with the adopted screening values, with some exceptions as discussed in the following sections.

### 6.1.1

#### *Onsite Soil*

- The shallow fill material in a single sample from the boundary of the B Station Power Block (AEC VA) at a depth of approximately 0.2 to 0.3 m bgl was observed to have black staining and a hydrocarbon odour. The corresponding laboratory results exceeded the human health screening level for carcinogenic PAHs.
- TRH C<sub>10</sub>-C<sub>16</sub> (excluding naphthalene) was detected at concentrations in excess of the adopted ecological screening value for commercial/industrial areas in individual soil samples collected from the boundary of the former A Station Demolition Area (AEC VB), the Fuel Oil Installation (AEC VG) and Coal Storage Area (AEC VJ).
- Benzo(a)pyrene was detected at concentrations in excess of the adopted ecological screening value for commercial/industrial areas in individual samples collected from the B Station Power Block (AEC VA) and Fuel Oil Installation (AEC VG) at a depth of 0.1 m bgl.
- Copper and zinc concentrations in excess of the ecological screening levels adopted for commercial/industrial areas were identified in individual soil samples collected from the B Station Power Block (AEC VA), Waste Oil Storage area (AEC VF), Fuel and the Water Treatment Plant Area (AEC VI), Chlorine Plant (AEC VM), Asbestos Landfills (AEC VP) and Fly Ash Plant (AEC VT). These impacts were not necessarily attributed to background conditions at the Site and could be related to onsite sources.
- Copper, nickel, zinc and benzo(a)pyrene in excess of the ecological screening levels adopted for ecologically significant areas were identified in individual samples collected from the Wyee Coal Unloader Area (AEC VN), Ash Dam (AEC VO) and Site Buffers and Boundaries (AEC VU).
- Significant quantities of fly-tipped waste, including drummed oils, household waste, wood, steel and plastic were observed in close proximity to the eastern boundary of the Wyee Coal Unloader Area (AEC VN). This area is accessible to the public via a short gravel road off Rutleys Road and the waste is likely to have been dumped illegally by members of the public.

- Asbestos was detected in individual shallow soil samples collected from within the Transformer Area (AEC VC), Chlorine Plant (AEC VM) and in the vicinity of the Asbestos Landfill (AEC VP) at concentrations in excess of the adopted human health screening values for fibrous asbestos and asbestos fines.

The results of the assessment do not suggest the presence of widespread asbestos contamination at the Site. It is noted however that as identified in the ASC NEPM (2013) the vertical boring of soils is not a comprehensive method via which to identify asbestos, however given the objectives of this assessment and the operational constraints, the assessment methodology adopted was considered appropriate. The absence of asbestos impacts across the Site cannot however be guaranteed on the basis of the results of this assessment. Similarly, as with any investigation of this nature, the potential exists for unidentified contamination to exist between the completed sampling locations both within and between AECs.

### 6.1.2

#### *Onsite Groundwater*

- TRH and chlorinated hydrocarbons were reported above the laboratory LOR in groundwater samples collected monitoring wells located around the boundary of the former A Station Demolition Area (AEC VB). The measured concentrations did not exceed the adopted screening values but may be indicative of the presence of unidentified impacts within the former A Station area.
- Groundwater samples from monitoring wells located around the boundary of the former A Station Demolition Area (AEC VB) and Chlorine Plant Area (AEC VM) reported PFOS concentrations in excess of the adopted human health screening level but not the adopted ecological screening level.
- Benzene was detected at concentrations in excess of the adopted human health (drinking water and recreational) screening values in groundwater samples collected from monitoring wells located in the Vehicle Refuelling Area (AECs VH) and a single sample collected from a well downgradient of the Asbestos Landfills (AEC VP).
- Where concentrations of metal(oids) in groundwater were measured above background values, impact generally appears to be localised in distinct areas of the site with the main potential source areas being the Coal Storage Area (AEC VJ) and the Ash Dam (AEC VO). Acidic groundwater conditions in the vicinity of the Vehicle Refuelling Area also appear to have contributed to the presence of elevated metal concentrations in groundwater, although it is noted that there are also areas of the Site where low pH conditions in groundwater have not resulted in metal concentrations in excess of background conditions.

- The majority of groundwater samples that reported concentrations of metals above the background values were collected from monitoring wells located downgradient of the Ash Dam which appears to present a primary source of arsenic and selenium to groundwater. The assessment results also suggest that the Ash Dam is a secondary source of cobalt, copper, lead, manganese, nickel and zinc, contributing to metal concentrations that are already generally elevated in background conditions. The highest concentrations were generally located in the vicinity of the toe drain, along the north western boundary of the Ash Dam and directly to the east of the Ash Dam.
- If disturbed alluvial sediments underlie the ash dam, these sediments may be contributing to elevated metal(loid) concentrations with potential sulfide oxidation in sediments resulting in acid sulfate conditions. Historical and current underground coal mining works in the area surrounding and underlying the majority of the Site could also have enlarge fracture surfaces within bedrock), further contributing to elevated metal(loid) concentrations observed in groundwater. The long term disposal of waste ash materials, which are known sources of metal contaminants, within the Ash Dam, may also have contributed to metal impacts in the underlying groundwater. The long term storage of coal materials within the Coal Storage Area may also have contributed to the observed metal impacts in groundwater in this area.

### 6.1.3 *Offsite Sediments and Surface Waters*

- Cadmium was identified in individual samples collected from within Wyee Creek, the control area and Wyee Bay at concentrations marginally in excess of the ISQG-low value. Two sediment samples collected from within Wyee Bay also returned copper concentrations marginally in excess of the ISQG-low values. The distribution and magnitude of these impacts is not suggestive of significant cadmium, copper and cobalt impacts in Lake Macquarie sediments as a result of the operation of the Vales Point Power Station.
- Exceedances of the adopted selenium ecological screening level were identified in numerous sediment samples collected from within the lower reaches of Wyee Creek and within Mannering Bay. The maximum selenium concentration reported in a sediment sample collected from Wyee Creek was 26 mg/kg, with the selenium concentrations measured in sediment samples collected from within Wyee Creek generally increasing along the Creek towards Mannering Bay. Relatively consistent concentrations of selenium were recorded throughout Mannering Bay, at up to 8 mg/kg.

- Copper and cobalt concentrations marginally in excess of the adopted ecological screening levels were identified in a number of surface water samples, but a clear link between these samples and the Site was not apparent in the data. Zinc concentrations exceeded the adopted ecological screening values in approximately 60% the surface water samples, including a number of the control area samples suggesting that background concentrations are elevated. Elevated background zinc concentrations may contribute to these concentrations in surface water. The samples collected from the upper reaches of Wyee Creek generally demonstrated the highest zinc concentrations, which may reflect a contribution from the Ash Dam but which may also reflect the fact that these samples were collected in a riparian rather than estuarine environment and as such are more likely to be influenced by increased sediment load.

## 6.2 *SUMMARY – DOES THE IDENTIFIED IMPACT REPRESENT A RISK TO HUMAN HEALTH AND/OR THE ENVIRONMENT?*

The approach to the screening of the data gathered in this assessment was to initially adopt the most conservative potential assessment values. The exceedances of the screening values outlined in *Section 4.10* were subsequently assessed on a case by case basis, in light of the specific characteristics of the individual samples and the AEC from which those samples were collected. The conclusions of these further assessments are presented in the following sections.

### 6.2.1 *Onsite Soil*

Benzo(a)pyrene was detected at concentrations in excess of the adopted human health and ecological screening level in a shallow soil sample on the boundary of the B Station Power Block (AEC VA). A single shallow soil sample collected in the vicinity of the Fuel Oil Installation (AEC VG) also reported benzo(a)pyrene at a concentration in excess of the adopted ecological screening level.

Benzo(a)pyrene is a non-volatile compound and therefore exposure to this chemical could only occur through direct contact with the soil or exposure to dust. The majority of these AECs are covered in hardstanding, including the area in which the impacted sampling locations were installed. On this basis, the PAH impacts identified in this location are considered unlikely to represent a significant risk to human health or the environment under the ongoing use of the Site as a Power Station. Actions to prevent direct contact with benzo(a)pyrene impacted soil should however be implemented during any subsurface works undertaken within the affected area of AEC VA, to minimise potential health risks to intrusive workers.

TRH C<sub>10</sub>-C<sub>16</sub> (excluding naphthalene) was detected at concentrations in excess of the adopted ecological screening value for commercial/industrial areas in individual soil samples collected from the boundary of the former A Station Demolition Area (AEC VB), the Fuel Oil Installation (AEC VG) and Coal Storage Area (AEC VJ). The ground surface within AEC VB and AEC VG was largely covered in hardstanding or gravel, including the area in which the impacted sampling locations were installed. The sampling location in AEC VJ was located on the south-western corner of the Coal Stockpile Area approximately 20 m from the edge of the stockpile area in an area of unsealed ground. PAH compounds were also detected in this sample, suggesting the possible contribution of stored coal to the identified TPH impacts in the vicinity of the Coal Stockpile, although visible coal particles were not identified in the sample. The vegetation in this area is limited to sparse areas of grass. On this basis, TRH impacts identified within these AECs are not considered to represent a significant risk to the terrestrial environment.

Copper and zinc concentrations in excess of the ecological screening levels adopted for commercial/industrial areas were identified in individual samples collected from the B Station Power Block (AEC VA), Waste Oil Storage area (AEC VF), Fuel and the Water Treatment Plant Area (AEC VI), Chlorine Plant (AEC VM), Asbestos Landfills (AEC VP) and Fly Ash Plant (AEC VT). With the exception of AEC VP, all of these exceedances were identified in fenced operational areas, either in areas covered with hardstanding or in areas with only limited vegetation. These impacts are therefore considered unlikely to represent a significant risk to the terrestrial environment assuming ongoing commercial industrial use in the current or similar configuration.

The copper and zinc concentrations in the shallow soil sample collected from AEC VP may suggest a hotspot of metals impact in the vicinity of the asbestos landfill, possibly as a result of the waste material buried in this area. The absence of elevated metal concentrations in other soil samples collected from within this AEC however, does not suggest widespread metal impacts in the areas surrounding the asbestos landfills.

Copper, nickel and zinc in excess of the ecological screening levels adopted for ecologically significant areas were identified in individual samples collected from the Wyee Rail Coal Unloader Area (AEC VN) and Site Buffers and Boundaries (AEC VU). The soil samples demonstrating exceedances of the ecological screening levels for areas of ecological significance within AEC VN and AEC VU are located within operational areas. The *Delta Coast Land Management Manual* (GHD, 2012) did not identify threatened or endangered species in these specific areas and hence the adoption of the screening values for the protection of areas of ecological significance is overly conservative for these samples.

As the measured concentrations did not exceed the adopted screening level for commercial/industrial areas, these impacts are not considered to be representative of a significant risk to the terrestrial environment under the ongoing use of the Site as a Power Station.

The concentrations of TRH (C10-C16 excluding naphthalene), benzo(a)pyrene, nickel and zinc measured in individual soil samples around the boundary of the Ash Dam (AEC VO) exceeded the ecological screening levels adopted for areas of ecological significance but not the commercial/industrial ecological screening levels. These results indicate that concentrations of TRH, PAH, nickel and zinc in soil around the boundary of the Ash Dam may be sufficient in some areas to adversely affect sensitive terrestrial organisms. Overall however, a significant adverse effect on the terrestrial environment is not predicted on the basis of these results. It is also noted that the Ash Dam receives licensed discharges of a variety of waste materials, including ash.

Chrysotile and amosite asbestos was detected in individual shallow soil samples collected from within the Transformer Area (AEC VC), Chlorine Plant (AEC VM) and the Asbestos Landfill (AEC VP) at concentrations in excess of the adopted human health screening values. The sampling locations within AEC VC and AEC VM are both in areas of bare gravel within the operational and are therefore accessible to Site employees. The sampling locations within AEC VP are also in areas of open ground and therefore accessible but are outside of the operational area, in a part of the Site known to be impacted by asbestos and only infrequently visited by Site employees.

All of these areas of asbestos impact may however represent a health risk if Site employees were to come into contact with them. ERM understands that Delta has subsequently recorded these areas in its Asbestos Register, for future management in line with the Delta Asbestos Management Procedures. The absence of asbestos within fill materials or upon surface soils in other areas across the Site also cannot be guaranteed on the basis of the results of this assessment.

## 6.2.2 *Onsite Groundwater*

### *Beneficial Uses*

Groundwater beneath the Site is not extracted for potable use and a search of licensed groundwater bores has not identified any potential groundwater extraction receptors in the immediate vicinity of the Site. The nearest registered groundwater bores to the Site are a domestic bore located approximately 700 m north of the operational area in Mannering Park and a stock watering bore located approximately 600 m north of the Ash Dam. The potential does however exist for unidentified groundwater bores to be present in the residential areas located immediately to the north, west and south of the Ash Dam and to the east of the Rail Coal Unloader Area.

The groundwater beneath the Site is not considered to be an aquatic environment of significance. Based on the topography and available hydrological information, groundwater beneath the operational area of the Site flows towards the outlet/inlet canal and the groundwater beneath the Ash Dam flows both to the north towards Mannering Bay and to the west towards Wyee Creek. The groundwater beneath the Wyee Rail Coal Unloader Area appears to flow to the east towards Lake Macquarie.

The ANZECC (2000) *marine ecological trigger values* were adopted in this assessment to evaluate risks to the marine environment (i.e. the inlet/outlet canal, Lake Macquarie, Wyee Creek and Mannering Bay). These screening levels also fulfil the requirement to report groundwater contamination across the Site, in accordance with the DECC (2009) *Guidelines on the Duty to Report Contamination under the Contaminated Land Management Act 1997* (refer to Section 4.10.2).

The NHMRC (2008) recreational screening values were adopted in this assessment to evaluate potential risks to recreational users of Mannering Bay and Lake Macquarie.

The NHMRC (2013) drinking water screening values were also adopted to evaluate potential risks to groundwater users in nearby residential communities. These values also fulfil the requirement to report groundwater contamination across the Site, in accordance with the DECC (2009) *Guidelines on the Duty to Report Contamination under the Contaminated Land Management Act 1997* (refer to Section 4.10.2).

#### *Hydrocarbons in Groundwater*

TRH and chlorinated hydrocarbons were reported above the laboratory LOR in groundwater samples collected from monitoring wells installed around the boundary of the former A Station Demolition Area (AEC VB). The measured concentrations did not exceed the adopted screening values but may be indicative of the presence of unidentified impacts within the former A Station area.

It is understood that once the demolition is complete, the A Station basement level concrete will remain and in other areas the ground surface will be covered with recycled crushed concrete and left vacant. On this basis unidentified hydrocarbon impacts within this area are unlikely to represent a risk to human health (i.e. assuming the land is left vacant and fenced).

Due to the presence of underground and overhead services and thick concrete (>0.6 m) on the transformer runways, a number of proposed sampling locations were unable to be installed along the northern boundary of the Former A Station. On this basis, the absence of hydrocarbons along the north western boundary of the former A Station Demolition Area could not be confirmed. Significant hydrocarbon impacts were not however identified in sediment or surface water samples collected from the mouth of the inlet/outlet canal. On this basis, potential unidentified hydrocarbon impacts within the former A Station Demolition Area do not appear to be resulting in significant impacts to the wider estuarine environment.

Benzene was detected at concentrations in excess of the adopted human health (drinking water) screening value in two groundwater sample collected from the Vehicle Refuelling Area (AECs VH). One of the benzene detections exceeded the adopted recreational screening values. The inferred groundwater flow direction in the area of the Vehicle Refuelling Depot is north east below the former A Station Power Block towards the inlet/outlet canal. In the absence of potable groundwater use in this area of the Site, these impacts are not considered to represent a significant potential risk to human health under the ongoing use of the Site as a Power Station. Benzene impacts were also not identified in sediment or surface water samples collected from the mouth of the inlet/outlet canal, indicating that these impacts are not likely to be impacting upon recreational users of Lake Macquarie.

Benzene was also identified in a single monitoring well in two samples collected from downgradient of the Asbestos Landfills (AEC VP) at a concentration marginally in excess of the adopted human health (drinking water) screening value. These detections may be related to the migration of impact associated with the waste materials disposed within the landfill. In the absence of potable groundwater use in this area, these marginal exceedances are not considered representative of a significant potential risk to human health.

#### *PFOS in Groundwater*

Wells located around the boundary of the former A Station Demolition Area (AEC VB) and Chlorine Plant Area (AEC VM) reported PFOS concentrations in excess of the adopted human health (drinking water) screening level but not the adopted ecological screening level. In the absence of potable groundwater use in this area, these exceedances are not considered representative of a significant potential risk to human health.

PFOS was detected in two monitoring wells around the boundary of the former A Station, both of which were located to the south east. PFOS was not detected in the monitoring wells located on the northern and western corners of the Former A Station Area.

As discussed above, a number of proposed sampling locations were unable to be installed along the northern boundary of the Former A Station and therefore the absence of PFOS in these areas cannot be confirmed.

#### *Metals in Groundwater*

Exceedances of the adopted human health (drinking water and recreational) screening levels were reported in groundwater for arsenic, lead, nickel manganese and selenium and exceedances of the adopted ecological screening levels were also reported for cobalt, copper, lead, nickel, selenium and zinc.

Where concentrations of metal(oids) in groundwater were measured above background values, impact generally appears to be localised in distinct areas of the site with the main potential source areas being the Vehicle Refuelling Depot (AEC VH), the Coal Storage Area (AEC VJ) and the Ash Dam (AEC VO). The majority of samples with concentrations reported above the background values were taken from monitoring wells located downgradient of the Ash Dam which appears to be a primary source of arsenic and selenium to groundwater and a secondary source of cobalt, copper, lead, manganese, nickel and zinc.

Potential risks to the marine environment and recreational users of the marine environment that may be associated with these metal impacts in groundwater are discussed in *Section 6.2.3*, with reference to the sediment and surface water data.

Licensed groundwater bores located within the vicinity of the Site are limited to a domestic bore located approximately 700 m north of the Site in Mannering Park and a former stock bore located approximately 1 km south west of the Power Station operational area and 600 m north of the Ash Dam in a Delta-owned wetland area. The inferred groundwater flow direction in the area of the Vehicle Refuelling Depot and Coal Storage Area is north east towards the inlet/outlet canal and Lake Macquarie. In the absence of potable groundwater use in the areas downgradient of the Vehicle Refuelling Area and Coal Storage Area, these elevated metal impacts in groundwater impacts are not considered to represent a significant potential risk to groundwater users.

Licensed groundwater bores are not present in the immediate vicinity of the Ash Dam, but rural residential and residential communities are located immediately to the north, west and south of the Ash Dam. The extraction of groundwater for potable, domestic, stock watering or commercial purposes in these areas may therefore potentially occur in the future. Risk to human health may be associated with the extraction of groundwater for use in the vicinity of the Ash Dam, particularly if that water were used for domestic purposes, although given the general elevated background metal concentrations measured across the Site, the groundwater beneath the adjacent properties is also likely to be generally unsuitable for potable use

It is recommended that this issue is discussed with the NSW EPA and NSW Office of Water, with the aim of implementing control measures to prevent the potable use of groundwater in the vicinity of the Ash Dam.

### 6.2.3 *Offsite Surface Water and Sediment*

Sediment and surface water samples were collected from within Wyee Creek, Mannering Bay, Wyee Bay and Chain Valley Bay to assess whether discharges from the Power Station, including runoff, groundwater discharge and operational surface water discharges have had an adverse effect on the marine environment surrounding the Site.

Exceedances of the adopted sediment screening levels for cadmium and copper were identified in individual samples but the distribution of these impacts is not suggestive of significant cadmium and cobalt impacts in Lake Macquarie sediments as a result of the operation of the Vales Point Power Station. Similarly, copper and cobalt concentrations marginally in excess of the adopted ecological screening levels were identified in a number of surface water samples, but a clear link between these samples and the Site was not apparent in the data. With the exception of selenium, the sediment and surface water results do not suggest that discharges from the Power Station have resulted in widespread significant risks to the marine environment or recreational users of the adjacent waterways, although it is noted that isolated areas of elevated impact may be present in close proximity to discharge points from the Site.

Exceedances of the adopted ecological selenium screening level (2 mg/kg) were identified in numerous sediment samples collected from within the lower reaches of Wyee Creek and within Mannering Bay. The maximum selenium concentration reported in a sediment sample collected from Wyee Creek was 26 mg/kg, with the selenium concentrations measured in sediment samples collected from within Wyee Creek generally increasing along the Creek towards Mannering Bay. Relatively consistent concentrations of selenium were recorded in sediment samples collected from throughout Mannering Bay, at up to 8 mg/kg. It is considered likely that discharges from the Ash Dam, potentially including licensed discharges, runoff and groundwater flow have contributed to these selenium impacts, although other potential sources within the catchment include mines, other power stations and other industries. The selenium concentrations measured in sediments located in Wyee Creek and Mannering Bay are therefore considered to have the potential to adversely impact upon marine organisms in these areas.

The *Delta Coast Land Management Manual* (GHD, 2012) indicates that State Environmental Planning Policy No. 14 (SEPP 14) wetlands are also located immediately to the north of the Ash Dam toe drain and along the creeks to the north of the Ash Dam. On the basis of the data collected in this assessment, these areas may potentially be adversely impacted upon by elevated selenium concentrations.

## 6.3

**SUMMARY – DOES THE IMPACT WARRANT NOTIFICATION UNDER THE CONTAMINATED LAND MANAGEMENT ACT 1997?**

Under Section 60 of the *CLM Act (1997)*, a person whose activities have contaminated land or a landowner whose land has been contaminated is required to notify NSW EPA when they become aware (or ought reasonably have been aware) of the contamination. The DECC (2009) *Guidelines on the Duty to Report Contamination under the Contaminated Land Management Act 1997*, state that a landowner or a person whose activities have contaminated land is required to notify NSW EPA that the land is contaminated if;

- the level of the contaminant exceeds the appropriate published screening level with respect to a current or approved use of the land, **and** people have been, or foreseeably will be, exposed to the contaminant; or
- the contamination meets a specific criterion prescribed by the regulations; or
- the contaminant has entered, or will foreseeably enter, neighbouring land, the atmosphere, groundwater or surface water, **and** the contamination exceeds, or will foreseeably exceed, an appropriate published screening value and will foreseeably continue to remain above that level.

The soil and groundwater results obtained in this assessment have been compared against the screening values specified in NSW DECC (2009) *Guidelines on the Duty to Report Contamination under the Contaminated Land Management Act 1997* and a number of exceedances have been identified.

Every exceedance of these screening values is not, however, required to be reported to the NSW EPA. If the exceedance is representative of background conditions; or offsite migration of contamination to an adjoining property has not occurred **and** any onsite contamination has been adequately addressed under the Environmental Planning and Assessment Act then reporting under the CLM Act is not required. Further to this, in the case of onsite soil contamination, if no plausible exposure pathway to people or the environment is present, reporting is also not required.

On the basis of the discussions outlined in *Section 6.1*, the constituents that have been identified in onsite soil, sediment, surface water and groundwater are generally not exceeding the relevant screening values as cited in NSW DECC (2009).

The identified impacts which do exceed the relevant screening values and are considered to warrant further consideration with regards to whether a duty to report may exist under the CLM Act include the following:

- Benzene detected at concentrations in excess of the adopted human health (drinking water and recreational) screening levels in two groundwater samples collected from the Vehicle Refuelling Area (AECs VH) and a single sample collected from downgradient of the Asbestos Landfills (AEC VP).
- PFOS detected at concentrations in excess of the adopted human health (drinking water) screening levels in a groundwater sample collected from around the boundary of the Former A Station Demolition Area (AEC VB) and a groundwater sample collected near the Chlorine Plant (AEC VM).
- Metals in groundwater detected at concentrations in excess of the adopted human health and/or ecological screening levels and not attributable to background conditions in groundwater at various locations across the Site. Metal impacts in groundwater generally appears to be localised in distinct areas of the site with the most likely potential source areas being the Vehicle Refuelling Depot (AEC VH), the Coal Storage Area (AEC VJ) and the Ash Dam (AEC VO).
- Exceedances of the selenium ecological screening level identified in numerous sediment samples collected from within the lower reaches of Wyee Creek and within Mannering Bay.

Each of these issues is discussed in further detail below.

### **6.3.1 Benzene in Groundwater - AEC VH and VP**

Benzene was detected in groundwater at concentrations above the adopted human health (drinking water) screening levels in two wells within the Vehicle Refuelling Area (AEC VH) and a single well installed downgradient of an Asbestos Landfill (AEC VP). It is considered likely that the benzene impacts in AEC VH are associated with the presence of USTs in this area and that the benzene impact in AEC VP is associated with the material buried within the asbestos landfill.

The concentrations of benzene measured in AEC VP were only marginally above the adopted screening level but were confirmed in a second round of sampling (May 2014). Notification to NSW EPA is therefore considered likely to be required.

Groundwater monitoring has been ongoing within AEC VH since 2010, when TRH(C<sub>10</sub> - C<sub>36</sub>) was identified at a concentration of 2540 µg/L, in a well installed to the north of the USTs. Hydrocarbon detections in the current assessment were limited to BTEX constituents and do not suggest the presence of a significant ongoing release in this area of the Site. Notification to NSW EPA is however considered likely to be required, as the detected concentration are significantly greater than the human health (drinking water) screening values and are likely to remain so for the foreseeable future.

It is considered unlikely in ERM's opinion that these impacts would be considered significant enough to warrant regulation by the NSW EPA given the absence of groundwater use onsite and the isolated nature of the detections. The inferred groundwater flow direction in the area of the Vehicle Refuelling Depot is north east below the former A Station Power Block towards the inlet/outlet canal and the Vehicle Refuelling Area is approximately 150 m from the canal.

### 6.3.2 *PFOS in Groundwater*

PFOS and PFOA were detected in groundwater at concentrations in excess of the adopted human health (drinking water) and ecological screening levels within the Former A Station Demolition Area (AEC VB) and Chlorine Plant (AEC VM). The likely sources of these impacts are fire training activities undertaken near the Chlorine Plant and the storage or use of firefighting foams within the operational area.

The adopted human health (drinking water) screening levels were obtained from US EPA (2014), with the adopted values being provisional health advisory concentrations, rather than regulatory guidelines. Similarly, the adopted ecological screening levels were obtained from RIVM (2010), with the adopted values only having been proposed as water quality standards in the Netherlands. As such, these values are not called up by section 60 of the CLM (1997) Act as prescribed levels of contamination requiring notification. It is also noted that the identified PFOS impacts are located within the operational area and do not appear to be migrating offsite. On this basis it is considered unlikely in ERM's opinion that these impacts would be considered significant enough to warrant regulation by the NSW EPA

### 6.3.3 *Metals in Groundwater*

Various metals were detected at concentrations above the human health (drinking water) and / or ecological screening values at a number of locations across the Site. Whilst some of the metals exceedances can be related to background concentrations, some elevated concentrations related to on-site sources have been identified.

The creation of ASS through the disturbance of alluvial sediments underlying the ash dam, historical and current underground coal mining works and the long term storage of waste ash materials and coal may have contributed to the observed metal impacts in groundwater in this area.

Where metals were identified in groundwater at concentrations above background levels, impact generally appears to be localised in distinct areas of the Site. Potential source areas appear to include the Coal Storage Area and the Ash Dam. Acidic groundwater conditions in the vicinity of the Vehicle Refuelling Area also appear to have contributed to the presence of elevated metal concentrations in groundwater.

With the exception of selenium discharges from the Ash Dam, the available data suggests that these impacts have not resulted in significant sediment or surface water contamination following discharge into the estuarine environment (see *Section 6.1.3*).

In ERM's professional experience it is NSW EPA's preference to regulate issues such as these under either the *POEO Act (1997)* or the *CLM Act (1997)* rather than both, and, in the case of licensed premises, it is usually the *POEO Act (1997)* which is preferred.

The majority of samples with concentrations reported above the background values were collected from monitoring wells located adjacent to the Ash Dam which appears to be a potential source of arsenic, selenium, and to a lesser extent cobalt, copper, lead, manganese, nickel and zinc. Seepage from the Ash Dam rehabilitated area at the v-notch weir located at the toe of the Ash Dam is currently regulated under the Site EPL. Similarly, the overboarding of the Ash Dam into the Wye Creek diversion channel is a licensed discharge point for the Site. Groundwater monitoring down-gradient of the Ash Dam has been undertaken by Aurecon (2014) in response to a NSW EPA request for an additional investigation in the form of a Pollution Reduction Programme (PRP) related to the elevated metal concentrations identified in groundwater.

ERM therefore considers that NSW EPA would most likely continue to manage this issue under the *POEO Act (1997)* via the Site EPL and associated PRP(s) and hence would not require formal notification under the CLM Act.

On 6 May 2014, Delta received a Vales Point Licence Variation Notice from the NSW EPA. The previous condition requirements to (a) identify any mitigation measures to be carried out to reduce the levels of parameters identified in groundwater and (b) provide estimated costings and proposed timeframes for implementation of mitigation measures, were removed as a part of this variation notice. This variation notice also included the requirement for monthly groundwater monitoring in the vicinity of the Ash Dam throughout 2014. It is recommended that Delta include groundwater results from within the Ash Dam Area (AEC VO) in the next scheduled report to the NSW EPA.

It is suggested that the NSW EPA should manage ongoing communications around the potable use of potentially impacted groundwater in the vicinity of the Ash Dam and downgradient areas, given the range of potential sources of metals in groundwater in this area and potential for the wider distribution of metals in groundwater.

#### 6.3.4 *Selenium in Sediment*

Selenium concentrations above the adopted screening levels and above background levels were identified in numerous sediment samples collected from within the lower reaches of Wyee Creek and within Mannering Bay. It is considered likely that discharges from the Ash Dam, potentially including licensed discharges, runoff and groundwater flow have contributed to these impacts. Other potential sources within the catchment include mines, other power stations and other industries.

It is noted that the sediment concentrations measured in the current investigation were of the same order of magnitude as those identified in historic investigations (e.g. Peters et al., 1999), suggesting that the selenium load in Wyee Creek and Mannering Bay sediments have not increased significantly in recent years. This is consistent with the history of the operation of the Ash Dam; prior to 1981 Vales Point discharged ash dam water direct to Mannering Bay and until 1996 ash dam water was diverted into Wyee Creek. From 1996, an ash return water system limited discharges into Wyee Creek and Mannering Bay, with discharges only occurring intermittently due to plant issues or significant rainfall events.

Delta has had a long history of consultation with the EPA and other authorities about selenium in local water bodies. Roach (2005) is a scientific paper published by the NSW EPA on the assessment of metals in sediments from Lake Macquarie and has a particular focus on the selenium impacts to sediment as a result of discharges from Power Stations. Aurecon (2010) indicated that data on the earlier testing of fish was provided by Delta and indicated that the selenium concentrations measured in bream were above the Generally Expected Levels (GELs) published by Food Standards Australian and New Zealand (2001). ERM understands that as a consequence of these results and subsequent communications between Delta and the NSW EPA (1998), warning signs were erected at Mannering and Wyee Bays in relation to long-term fish consumption for those areas.

The adopted sediment screening levels were obtained from the British Columbia Ministry of Environment (2001) Ambient Water Quality Guidelines. These values are not called up by section 60 of the CLM (1997) Act as prescribed levels of contamination requiring notification.

It is noted that the levels of selenium in the sediment are lower than the levels prescribed in the ASC NEPM (2013) for the assessment of residential soil (200 mg/kg) and therefore would not trigger notification if the offsite sediment was evaluated as 'soil on neighbouring land' for the purposes of assessing the duty to report requirements under the CLM Act (1997).

On the basis of the above factors, it is considered that the selenium impacts in sediment in Wyee Creek and Mannering Bay do not require notification to the NSW EPA under the CLM Act (1997).

### 6.3.5

#### *Summary – Is Material Remediation or Management Likely to be Required?*

Based on the results of this assessment, the issues where potentially material remediation, management or further assessment on a per source basis may be required relate to the metals in groundwater in the vicinity of the Ash Dam. The elevated metal concentrations in the vicinity of the Ash Dam toe drain have also already been identified by the NSW EPA in the form of a PRP and investigations into this issue in the vicinity of the Ash Dam toe drain were ongoing at the time of the current assessment.

Elevated metal concentrations were identified in groundwater samples collected around the entire perimeter of the Ash Dam, with the highest concentrations generally located in the vicinity of the toe drain, along the north western boundary of the Ash Dam and directly to the east of the Ash Dam. With the exception of selenium, the sediment and surface water results do not suggest that discharges from the Power Station have resulted in widespread significant risks to the marine environment or recreational users of the adjacent waterways.

The metal impacts in the vicinity of the Ash Dam are currently managed by Delta. This is an ongoing issue which could, under a realistic worst case scenario, be material. Estimates for ongoing costs have not been made, as these costs will be dependent on outcome of the relevant PRP and ongoing discussions with NSW EPA. It is also noted that elevated background metal concentrations are present in the area and the potential exists for inputs from historic mining activities to be material.

Further assessment and remediation or management may be required to address the asbestos impacts identified in surface soil in the vicinity of the Transformer Area (AEC VC) and Chlorine Plant (AEC VM). It is however considered unlikely that this work would exceed the material threshold.

It is noted that conducting intrusive investigations within the B Station, Transformer Area and Former A Station demolition Area was not possible, due to the potential health and safety issues associated with the presence of underground services in these areas.

The investigation of these AECs was therefore limited to assessment around the boundaries. Further assessment and remediation may be required to address unidentified soil and groundwater impacts within these areas if the landuse of these portions of the Site was to change in the future. It is possible that costs related to this work could exceed the material threshold. A detailed costing for such works has not been prepared since this would be dependent on the nature and layout of the proposed use which cannot be predicted at this point in time.

Fly-tipped waste was identified on the soil surface on the eastern boundary of the Wyee Rail Coal Unloader Area (AEC VN) adjacent to the publically accessible roadway. These impacts will require addressing and action to prevent further waste dumping in the future should also be considered. The costs of these activities are not however anticipated to be material.

The remediation of the selenium impacts in Wyee Creek or Mannering Bay sediments is not considered to be feasible, given the nature of the estuarine environment in these areas; removing impacted sediment from would be highly disruptive to the estuarine environment and is considered likely to result in more adverse effects on the estuarine ecology than leaving the impacts in situ. This is particularly the case due to the presence of seagrass habitats and mangrove areas within Wyee Bay, Mannering Bay and Wyee Creek (Bio-analysis, 2013) (GHD, 2012).

#### 6.4

##### ***SUMMARY – IS THE DATA SUITABLE TO PROVIDE A BASELINE OF ENVIRONMENTAL CONDITIONS AT THE SITE AND IMMEDIATE SURROUNDING RECEIVING ENVIRONMENTS***

The data presented in the ESA was considered to generally be of a suitable quality and completeness to provide a baseline of environmental conditions at the Site as at or near the time of the transaction.

It is noted that the majority of the locations proposed in the Preliminary ESA were able to be advanced, with the exception of the locations listed in *Section 4.1*. The main constraints on the implementation of the Stage 2 program were the presence of subsurface and overhead utilities and access restrictions within the buffer zone. The proposed Stage 2 program included soil samples from 188 locations and groundwater samples from 133 locations. The completed Stage 2 program included soil samples from 173 locations and groundwater samples from 89 locations. An evaluation of the proposed and completed investigation locations for each AEC is provided in *Table 8 of Annex B* and on this basis it is considered that the number and distribution of completed boreholes and monitoring wells is sufficient for characterising soil and groundwater conditions for the purpose of this baseline assessment.

The results of the assessment do not suggest the presence of widespread asbestos contamination at the Site. It is noted however that as identified in the ASC NEPM (2013) the vertical boring of soils is not a comprehensive method via which to identify asbestos, however given the objectives of this assessment and the operational constraints, the assessment methodology adopted was considered appropriate. The absence of asbestos impacts across the Site cannot however be guaranteed on the basis of the results of this assessment. As with any investigation of this nature, the potential exists for unidentified contamination to exist between the completed sampling locations both within and between AECs. In particular, it is noted that conducting intrusive investigations within the B Station, Transformer Area and Former A Station demolition Area was not possible, due to the health and safety issues associated with the presence of underground services in these areas. The investigation of these AECs was therefore limited to assessment around the boundaries and unidentified soil and groundwater impacts may be present within these areas.

In addition, the installation of boreholes along an approximately 2 km long stretch of the south western boundary of the Ash Dam was not possible, due to the presence of a Jemena high pressure gas pipeline in the subsurface. In the absence of additional contaminant source areas in this area of the AEC, contamination along the south western boundary is likely to be consistent with that identified along other boundaries of the Ash Dam (i.e. limited to exceedances of the adopted human health and ecological screening levels for metals in groundwater and potentially soil).

On the basis of the above discussion, the data collected during this assessment is considered to be suitable to provide a baseline of environmental conditions at the Site as at or near the time of the transaction.

**CONCLUSIONS**

ERM completed a Stage 2 ESA at Vales Point Power Station in order to develop a baseline assessment of environmental conditions at the Site as at or near the time of the transaction. Soil, groundwater, surface water and sediment data were compared against published environmental quality levels to provide a screening level assessment of potential risks to identified human and environmental receptors. The following conclusions were made based on the data collected during the investigation:

- The key impacts identified included benzene in groundwater in the Vehicle Refuelling Area and downgradient of the Asbestos Landfills, PFOS (a chemical associated with firefighting foams) in groundwater around the boundary of the former A Station Demolition Area and the Chlorine Plant and TRH, benzo(a)pyrene, asbestos and metals in individual soil samples across the Site.
- Selenium concentrations above adopted screening values were also identified in sediment samples collected from within Wyee Creek and Mannering Lake. It is considered likely that discharges from the Ash Dam, potentially including licensed discharges, runoff and groundwater flow have partially contributed to these impacts. Other potential sources within the catchment include mines, other power stations and other industries. The selenium concentrations identified in the current assessment were of the same order of magnitude as those identified in historic investigations suggesting that, as a result of changes to the management of discharges from the Ash Dam, the selenium load in Wyee Creek and Mannering Bay sediments has not increased significantly in recent years.
- TRH and chlorinated hydrocarbons were reported in groundwater samples collected around the boundary of former A Station Demolition Area. The former A Station area could not be investigated directly due to ongoing demolition work and thus a potential data gap exists in this area).
- Various metals were identified at concentrations in excess of the adopted screening values across the Site. Where metals were identified above background concentrations, impact generally appears to be localised in distinct areas of the Site. Potential source areas appear to include the Ash Dam and Coal Storage Area, where the creation of ASS conditions through the disturbance of alluvial sediments, historical and current underground coal mining works and/or the long term storage of waste ash materials and coal may have contributed to the observed metal impacts in groundwater. Acidic groundwater conditions in the vicinity of the Vehicle Refuelling Area also appear to have contributed to the presence of elevated metal concentrations in groundwater in that part of the Site.

- Fly-tipped waste was identified on the soil surface on the eastern boundary of the Wyee Rail Coal Unloader Area along the publically accessible roadway.
- With the exception of the selenium impacts identified in sediment (see below), the impacts identified in soil and groundwater at the sites are generally unlikely to represent a significant risk to human health and/or the environment given appropriate ongoing management based on the current and continued use of the Site as a Power Station.
- The selenium concentrations measured in Wyee Creek and Mannering Bay have the potential to adversely affect marine organisms in these areas. ERM understands that elevated selenium concentrations have previously been measured in fish collected from Mannering Bay and that the NSW EPA has previously been made aware of these impacts. Signage has been posted along Rutleys Road warning the public about the potential health risks associated with the consumption of fish from this area.
- Licensed groundwater bores are not present in the immediate vicinity of the Ash Dam, but rural residential and residential communities are located immediately to the north, west and south. If the extraction of groundwater for potable, domestic, stock watering or commercial purposes was to occur in these areas in the future, the elevated metal concentrations in groundwater may be associated with risks to human health or livestock. It is recommended that this issue is raised with the NSW EPA when discussing the next scheduled deliverable associated with PRP being implemented in the Ash Dam area. It is suggested that the NSW EPA should manage ongoing communications on this issue, given the range of potential sources of metals in groundwater in this area.
- Asbestos was detected in individual shallow soil samples collected from bare ground within the Transformer Area, Chlorine Plant and around the boundaries of the Asbestos Landfill at concentrations in excess of the adopted human health screening values. All of these areas of asbestos impact may represent a health risk if Site employees were to come into contact with them. ERM understands that Delta has recorded these sites in its Asbestos Register and that these impacts shall be managed in accordance with Delta's existing asbestos management procedures.
- The metal impacts in the vicinity of the Ash Dam are currently managed by Delta. This is an ongoing issue which could, under a worst case scenario, be material. Estimates for ongoing costs have not been made, as these costs will be dependent on outcome of the relevant PRP and ongoing discussions with NSW EPA. It is also noted that elevated background metal concentrations are present in the area and the potential exists for inputs from historic mining activities to be material.

- It is noted that conducting intrusive investigations within the B Station, Transformer Area and Former A Station demolition Area was not possible, due to the potential health and safety issues associated with the presence of underground services in this areas. Further potentially material assessment and remediation may be required to address unidentified soil and groundwater impacts within these areas if the landuse of the Site was to change in the future.
- ERM considers that NSW EPA would most likely continue to manage the metals in groundwater in the vicinity of the Ash Dam under the POEO Act (1997) via the Site EPL. The Vales Point EPL includes the requirement for monthly groundwater monitoring in the vicinity of the Ash Dam throughout 2014. It is recommended that Delta include groundwater results from within the Ash Dam Area (AEC VO) in the next scheduled report to the NSW EPA.
- It is recommended that the NSW EPA is notified regarding the benzene concentrations measured in excess of the adopted human health (drinking water) screening levels in the Vehicle Refuelling Area (AEC VH) and Asbestos Landfills (AEC VP). On the basis that the identified benzene impacts do not appear to be migrating offsite, it is considered unlikely in ERM's opinion that these impacts would be considered significant enough to warrant regulation by the NSW EPA.
- The data presented in this Stage 2 ESA was generally considered to be of a suitable quality and completeness to provide a baseline of environmental conditions at the Site and immediate surrounding receiving environments.

Stage	Area	Sampling Element	SB	MW	SS	SW	Total Locations	Existing MWs	SBs from other AECs	Wells From Adjacent AECs	Total GW Locations (Existing + New)	Total Soil Locations (SB + MW)	Total Water Locations (Existing MW + MW + SW)	Total Soil/Sed Locations (SB + MW + SS)	Operational Constraints and Details of Areal Coverage
Proposed	VA	B Station Power Block	4	8	0	0	12	0	2	4	8	12	8	12	The abandoned locations were positioned to the south west of the B Station in the vicinity of the emergency diesel tank. The locations were abandoned due to the proximity of multiple overhead and underground services and the absence of safe alternate locations to relocate to in the area.
Actual	VA	B Station Power Block	3	6	0	0	9	0	1	2	6	9	6	9	Coverage of this area is provided by VC_MW03 and VB_MW05.
Proposed	VB	Former A Station	3	7	0	0	10	0	1	6	7	10	7	10	Four of the abandoned locations were positioned along the transformer runway, in an area containing deep stormwater drains and very thick concrete rails used to move transformers. One of the abandoned locations was positioned to the east of the administration building in close proximity to a high voltage kiosk which was not shown on . No safe location alternate location was identified to install these locations as area is confined by the canal and former A station.
Actual	VB	Former A Station	1	4	0	0	5	0	0	4	4	5	4	5	Coverage of the southern boundary of this AEC is provided by locations installed within AECs VH and VI. Only two locations were able to be installed on the northern boundary of this AEC.
Proposed	VC	Transformer Area	2	5	0	0	7	0	1	3	5	7	5	7	One soil bore was abandoned and one groundwater monitoring well was installed as a shallow soil bore due to the presence of 4, 2 m diameter cooling water inlet channels running directly under the locations, approximately 3 -4 metres below ground level and hence not able to be picked up by GPR. Alternate locations were not identified due to the presence of the canal to the north and the transformers and ASTs to the south.
Actual	VC	Transformer Area	2	4	0	0	6	0	0	2	4	6	4	6	Sufficient coverage of this area is provided by the locations installed.
Proposed	VD	Main Dangerous Good Store	2	5	0	0	7	0	1	7	5	7	5	7	All locations proposed were completed.
Actual	VD	Main Dangerous Good Store	2	5	0	0	7	0	1	7	5	7	5	7	Sufficient coverage of this area is provided by the locations installed
Proposed	VE	Contaminated Water Treatment Plant	1	3	0	0	4	0	0	3	3	4	3	4	One monitoring well was completed as a shallow soil bore, due to the presence of multiple subservice and overhead services and the presence of a steep slope on one side.
Actual	VE	Contaminated Water Treatment Plant	2	2	0	0	4	0	0	3	2	4	2	4	Sufficient coverage of this area is provided by the locations installed.
Proposed	VF	Waste Oil Storage Area	0	3	0	0	3	0	2	3	3	3	3	3	All locations proposed were completed.
Actual	VF	Waste Oil Storage Area	0	3	0	0	3	0	2	3	3	3	3	3	Sufficient coverage of this area is provided by the locations installed
Proposed	VG	Fuel Oil Installation	0	4	0	0	4	0	1	0	4	4	4	4	All locations proposed were completed.
Actual	VG	Fuel Oil Installation	0	4	0	0	4	0	1	0	4	4	4	4	Sufficient coverage of this area is provided by the locations installed
Proposed	VH	Vehicle Refuelling Depot	0	0	0	0	0	10	0	3	10	0	10	0	All existing monitoring wells were identified
Actual	VH	Vehicle Refuelling Depot	0	0	0	0	0	10	0	2	10	0	10	0	Sufficient coverage of this area is provided by the locations installed
Proposed	VI	Water Treatment Plant Area	2	3	0	0	5	0	0	5	3	5	3	5	Two locations were abandoned and one location was installed as a shallow soil bore due to the proximity of overhead cable trays and underground services.
Actual	VI	Water Treatment Plant Area	1	2	0	0	3	0	0	4	2	3	2	3	Coverage of this area is provided by VT_MW03 and VB_MW01.
Proposed	VJ	Coal Storage Area	4	10	0	0	14	0	6	11	10	14	10	14	All locations proposed were completed.
Actual	VJ	Coal Storage Area	4	10	0	0	14	0	6	11	10	14	10	14	Sufficient coverage of this area is provided by the locations installed
Proposed	VK	Mobile Plant Maintenance and Refuelling Areas	2	7	0	0	9	0	1	5	7	9	7	9	All locations proposed were completed.
Actual	VK	Mobile Plant Maintenance and Refuelling Areas	2	7	0	0	9	0	1	5	7	9	7	9	Sufficient coverage of this area is provided by the locations installed
Proposed	VL	Sewage Treatment Plant	1	3	0	0	4	1	1	2	4	4	4	4	One location was installed as a shallow soil bore, due to the proximity of main electrical services
Actual	VL	Sewage Treatment Plant	1	3	0	0	4	0	1	2	3	4	3	4	Sufficient coverage of this area is provided by the locations installed
Proposed	VM	Chlorine Plant	1	5	0	0	6	0	0	1	5	6	5	6	Two monitoring wells and one soil bore were installed as shallow soil bores due to the presence of multiple underground and overhead services.

Stage	Area	Sampling Element	SB	MW	SS	SW	Total Locations	Existing MWs	SBs from other AECs	Wells From Adjacent AECs	Total GW Locations (Existing + New)	Total Soil Locations (SB + MW)	Total Water Locations (Existing MW + MW + SW)	Total Soil/Sed Locations (SB + MW + SS)	Operational Constraints and Details of Areal Coverage
Actual	VM	Chlorine Plant	3	3	0	0	6	0	0	1	3	6	3	6	VM_MW01 and VM_MW03 provide sufficient coverage of groundwater conditions in this area
Proposed	VN	Rail Coal Unloader Area and Coal Conveyors	5	12	0	0	17	0	6	4	12	17	12	17	Two locations were abandoned due to flooding in the area and therefore lack of access.
Actual	VN	Rail Coal Unloader Area and Coal Conveyors	5	10	0	0	15	0	0	0	10	15	10	15	The abandoned locations were positioned along the eastern boundary of the AEC, away from
Proposed	VO	Ash Dam	3	20	0	0	23	3		5	23	23	23	23	One monitoring well was changed to a soil bore due to proximity to a Jemena gas pipeline. One soil bore was abandoned due to flooding in the area and therefore lack of access
Actual	VO	Ash Dam	2	19	0	0	21	3	11	3	22	21	22	21	Coverage of the area surrounding the abandoned soil bore is provided by VO_MW14. Coverage of the area surrounding the monitoring well which was changed to a soil bore is provided by VU_MW17
Proposed	VP	Asbestos Landfills	10	2	0	0	12	0	0	2	2	12	2	12	All locations proposed were completed.
Actual	VP	Asbestos Landfills	10	2	0	0	12	0	0	2	2	12	2	12	Sufficient coverage of this area is provided by the locations installed
Proposed	VQ	Asbestos Pipeline	12	0	0	0	12	0	0	7	0	12	0	12	All locations proposed were completed.
Actual	VQ	Asbestos Pipeline	12	0	0	0	12	0	0	7	0	12	0	12	Sufficient coverage of this area is provided by the locations installed
Proposed	VR	Sediments in Surrounding Waterways	0	0	23	23	46	0	0	0	0	0	23	23	All locations proposed were completed.
Actual	VR	Sediments in Surrounding Waterways	0	0	23	23	46	0	0	0	0	0	23	23	Sufficient coverage of this area is provided by the locations installed
Proposed	VS	TransGrid Switchyard	1	5	0	0	6	0	2	9	5	6	5	6	All locations proposed were completed.
Actual	VS	TransGrid Switchyard	1	5	0	0	6	0	1	7	5	6	5	6	Sufficient coverage of this area is provided by the locations installed
Proposed	VT	Fly Ash Plant	0	3	0	0	3	0	3	4	3	3	3	3	One monitoring well was changed to a soil bore due to steep topography and truck movements in the area.
Actual	VT	Fly Ash Plant	1	2	0	0	3	0	3	3	2	3	2	3	Coverage of this area is provided by VT_MW03B
Proposed	VU	Buffer Lands and Boundaries	3	20	0	0	23	0	2	15	20	23	20	23	Two monitoring well locations were changed to soil bores and one was abandoned due to proximity to a Jemena gas pipeline and access difficulties.
Actual	VU	Buffer Lands and Boundaries	5	17	0	0	22	0	2	14	17	22	17	22	The two monitoring wells located in close proximity to the Jemena pipeline are on the south western boundary of the Ash Dam. Due to the presence of the pipeline an approximately 2 km stretch of the site boundary has not been covered by groundwater monitoring wells.
<b>Total Proposed</b>			55	133	23	23	211	13			78	93	146	258	
<b>Total Proposed</b>			57	108	23	23	211	13			89	173	118	201	
<b>Difference</b>			2	-25	0	0	0	0			11	80	-28	-57	

Notes:  
 SB = Soil Bore (not including bores converted to MW)  
 MW = Soil Bore converted to Groundwater Monitoring Well  
 SS = Sediment Sample  
 Total Locations = SB + MW (or SS)  
 Existing MWs = based on available reports and assumes wells are operational for sampling.  
 Total MWs = proposed wells + existing wells

Annex C

Refined CSM

**LEGEND**

- Primary Source
- Secondary Source
- Release Mechanism
- Exposure Media
- Incomplete Pathway

- Potential Source Pathway Receptor Linkages identified in the Preliminary ESA but discounted on the basis of the data collected in the Stage 2 ESA
- Potential Source Pathway Receptor Linkages not able to be discounted on the basis of the data collected in the Stage 2 ESA
- Potential Source Pathway Receptor Linkages present in relation to asbestos contamination but ERM understands that these will be managed via Delta's existing asbestos management procedures

## 0Equipment Certification Report – TPS 90FLMV Water Quality Meter

This Water Quality Meter has been performance checked and calibrated as follows:

Sensor	Concentration	Span 1	Span 2	Traceability Lot #	Pass?
pH	7.00H / pH 4.00	7.00 pH	4.00 pH	/	<input checked="" type="checkbox"/>
Conductivity	2.76mS/cm	6.00 mS/cm	2.76 mS/cm		<input checked="" type="checkbox"/>
TDS	36 ppk	0.0 ppk	36.0 ppk		<input checked="" type="checkbox"/>
Dissolved Oxygen	Sodium Sulphite / Air	0.00 ppm in Sodium Sulphite	8.74 ppm Saturation in Air		<input checked="" type="checkbox"/>

**Check only**

Redox (ORP) *	Electrode operability test	240mV +/- 10%	236 mV		<input checked="" type="checkbox"/>
---------------	----------------------------	---------------	--------	--	-------------------------------------

\* This meter uses an Ag/AgCl ORP electrode. To convert readings to SHE (Standard Hydrogen Electrode), add 199mV to the mV reading.

- Battery Status 7.2 (min 7.2V)  Temperature 21.8 °C  
 Electrical Safety Tag attached (AS/NZS 3760)  Electrodes Cleaned and checked

## GROUNDWATER MONITORING REPORT

Client: 27.03.14	Job No: <sup>nr</sup> Symphony
Project: 237747	Well ID: VT-MW03b
Location: Moxgand Hwy Ash	Total Depth (m): 7.050

**WELL FINISH:**  
 Monument       PVC Stand Pipe       Gatic Cover       Other:

**WELL DEVELOPMENT:**

	Stage 1	Stage 2		Stage 1	Stage 2
Sampler:	S. NUTHALAPATI		Before	SWL (m): 5.370	
Date:	27.03.14			Time: 8:25	
Well Atmosphere (ppm):	-		After	SWL (m): 6.140	
Method:	MONSOON			Time: 9:10	
Total Volume Removed (L):	42 L		Depth to Product (m):	-	

Total Depth to Bottom of Well - Before & After Development (m): 7.050 & 7.050

Comments (Before and After Developing): 2 well volume: 4.0L (approx). Initial gasping showed Appearance and Odours: no indication of silt at the bottom of the well. Initial Other: Purging shows moderate volume of bright orange fine silt in water. Rinsed 42L. Cloudy.

**WELL PURGING: VT-MW01**

Sampler:	S. NUTHALAPATI	Before	SWL (m): 5.245
Date:	27.03.14		Time: 9:18
Well Atmosphere (ppm):	-	After	SWL (m): 6.200
Method:	MONSOON		Time: 9:50
Total Volume Removed (L):		Depth to Product (m):	7.540 & 7.540

**WELL PURGING - FIELD PARAMETER DATA**

Vol. Removed (L):	Time:	Temp:	DO (% or ppm):	EC (µS or mS):	pH:	Eh (mV):

Comments: one well volume: 4.0L (approx). Removed 10L after first purging. Bright Appearance and Odours: orange, odourless, fine silt water. Rinsed: 42L. Cloudy. Other:

**WELL SAMPLING:**

Annex F

QA/QC

The objective of this data assessment is to evaluate the quality of data gathered during the project. This process has been undertaken to assess whether the sample data is of a suitable standard to be utilised in this report. The data assessment consists of comparing field and laboratory QA/QC results to documented NEPM, ANZECC, USEPA SW-846 guidelines, USEPA CLP National Functional Guidelines for Inorganic and Organic Data Review, and other internationally recognised publications. The data assessment has been prepared in accordance with the NEPC (2013) *National Environmental Protection (Assessment of Site Contamination) Measure 1999* and NSW EPA (1997) *Guidelines for Consultants Reporting on Contaminated Sites* and NSW DEC (2006) *Guidelines for the NSW Site Auditor Scheme (2<sup>nd</sup> Edition)*. Particular reference is made to the PARCC parameters (precision, accuracy, representativeness, completeness and comparability) in evaluating the data quality.

Table F1 presents the degree of QA/QC pertinent to the field investigations.

Table F2 presents the degree of QA/QC pertinent to the laboratory program.

The data quality indicators of precision, accuracy, representativeness, comparability and completeness have been assessed as shown in Table F3.

Table F1 Field QA/QC Assessment

QA/QC Criterion	Comments
QA/QC program includes replicate samples	<p>Field quality control samples including 62 intra-laboratory duplicates (33 soil, 22 water, and 7 sediment) were analysed to assess the suitability of the data. 21 inter-laboratory duplicate samples (12 soil, 5 water and 4 sediment) were sent to a secondary laboratory.</p> <p>The number of samples analysed, including QA/QC replicates, are presented in Table F.4 and Table F.4(a).</p> <p>Duplicate samples were collected following ERM standard operating procedures, at the required ratio of at least one duplicate for 10 primary samples (10%) and one inter lab duplicate for every 20 primary samples (5%) for sediment samples only. For soils the ratio was 8% and 3% and for water samples, the ratio was 15% and 3%. For additional water samples collected 27/05/2014, the ratio was 33% and 33%.</p> <p>The non-conformance with the ERM standard operating procedure for soil and water duplicates and inter lab duplicates is considered to be minor, with many of the soil samples found to have concentrations below the limit of reporting.</p> <p>The sediment sampling undertaken on this site was completed at the same time as the sediment sampling for Colongra Power Station and sediment samples for both sites were sent to their respective laboratories within the same batches. For the total of sediments from Vales Point Power Station and Colongra Power Station, the ratios for sediment duplicates and inter lab duplicates were 18% and 11% respectively. This is considered to be in accordance with the ERM standard operating procedure.</p>
All relevant media assessed	Soil, sediment, and groundwater and surface water samples were collected from all identified Areas of Environmental Concern (AECs) as part of the characterisation program.

QA/QC Criterion	Comments
Appropriateness of sampling strategy	Based on the results of the ERM PESA (2014) and consideration of the intended approach to establishing a baseline of soil and groundwater contamination, the most appropriate sampling design was considered to be a judgemental (targeted) sampling of soil, groundwater, surface water and sediments at the established AECs for the Site. The spatial coverage achieved was considered to be suitable in achieving the project objectives within the constraints of safe and reasonable access. Where investigation locations were not able to be completed due to logistical issues, these were discussed in the report.
Sample collection, handling and transportation procedures.	Samples were collected, handled and transported following ERM standard operating procedures as described in the <i>Vales Point PESA [Reference 0227637RP01]</i> (ERM, 2014).
Sampling is representative of site conditions	<p>Representative samples were collected from all identified AECs including soil, groundwater, surface water and sediment.</p> <ul style="list-style-type: none"> <li>• Field screening - including PID measurements and visual/olfactory observations were noted throughout the drilled profile.</li> <li>• Sample Collection - samples were generally collected at the surface and 0.5 m intervals for the first 2 m and every 1 m thereafter, or where changes in lithological units or significant contamination were noted.</li> <li>• Sample Analysis - generally one shallow sample targeting fill and the zone of surface impacts (0-1.5 m bgl) and one deeper sample targeting natural soil/geology between vadose zone and water bearing unit. Shallow bedrock and refusal on rubble occasionally restricted collecting a second sample from the deeper soil profile.</li> <li>• Groundwater - selected soil bores were converted to monitoring wells and groundwater samples were collected. Groundwater monitoring wells were selected to target areas with potential impact or boundary/background areas and to aid in the assessment of groundwater flow directions.</li> </ul>
Field QA/QC plan	<p>The sampling team comprised suitably qualified and experienced ERM environmental scientists.</p> <p>Borehole logs and/or other sampling records were completed, describing the media sampled, the duplicate types and sampling locations.</p> <p>Samples were collected using a combination of hand auger (during NDD), push tube, and where geology necessitated hollow and solid flight auger drilling techniques. Soil samples were placed in laboratory supplied sample jars, stored in an insulated cooler, and forwarded to the NATA accredited laboratory under COC conditions. The methods used to collect the samples, the types of sample containers, preservation techniques and custody protocols were documented appropriately.</p> <p>Inter-laboratory and intra-laboratory analytical results and their relative percentage differences (RPDs) are presented in <i>Table F5 and F6 Series</i>. Where samples were collected from push tube cores, samples were not homogenised prior to splitting to minimise loss of volatile analytes. Volatile analytes may have been lost where samples were collected from hand augers, hollow and solid flight augers. The RPDs of the duplicate sample pairs were generally below the acceptance limits (30% RPD where one or both values were greater than 10 x LOR or 50% RPD where both values less than 10 x LOR).</p>

QA/QC Criterion	Comments
	<p>An evaluation of the analytical data indicated that the data was generally of acceptable precision and accuracy. Minor exceedances of RPD acceptable limits were noted for some primary and duplicate sample pairs, as presented in <i>Table F5 and F6 Series</i> and summarised below.</p> <p>Decontamination procedures were implemented between the collection of different groundwater samples. Cross contamination was not considered likely during soil sampling from disposable push tube liners, and decontamination was not undertaken. The processes followed were considered suitable for minimising cross-contamination during sampling.</p> <p>Rinsate blanks were collected to demonstrate the efficacy of the decontamination procedures during groundwater sampling (refer to <i>Tables F7a to F7g</i>).</p> <p>Contaminants of concern were below the laboratory limit of reporting in the rinsate samples with the minor exceptions presented in <i>Table F7a to F7f</i> and summarised below.</p> <p>Trip blank samples were collected as part of this investigation. All COPCs were reported below the laboratory LOR (refer to <i>Table F8 Series</i>).</p> <p>Trip spikes were collected as part of this investigation. All COPCs were reported within the acceptable range apart from minor exceptions presented in <i>Table F9</i> and presented below.</p> <p>Field instruments used as part of this investigation were appropriately calibrated and used according to the manufacturers' instructions. Calibration certificates are provided in <i>Annex E</i>.</p>

#### *Field QA/QC Exceedances*

Minor exceedances of field duplicate RPD acceptable limits were noted for primary and duplicate samples, as presented in *Table F5 and F6 Series*. Elevated relative percentage differences (RPDs) between soil/sediment duplicate samples were generally attributed to the heterogeneity of the soil matrix, but also for several analytes, the concentrations for one of the samples was below the limit of reporting for the laboratory and the other was close to the limit of reporting for the separate laboratory. The analytes were below the adopted guideline value (where available) and therefore these non-conformances were not expected to materially affect the outcomes of this investigation.

Elevated RPDs between some groundwater duplicate sample pairs were generally associated with heavy metal COPCs. The range in metal concentrations are considered representative of background levels. These non-conformances were not expected to materially affect the outcomes of this investigation.

Rinsate samples collected during soil sampling were collected from the Hand Auger or a trowel following decontamination. Rinsate samples collected during groundwater sampling were taken following decontamination of the interface probe, or from the micropurge pump (when used). Of the 38 rinsate samples collected during the soil, sediment, groundwater and surface water sampling program, seven rinsate samples were reported to contain minor concentrations of contaminants. The samples with detections of contaminants were:

- R03\_260314\_SO, 26/03/2014 for zinc (6 ug/L)
- R01\_21.3.14\_WG, 21/03/2014 for Chromium (III + VI), Copper and Nickel (40, 4 and 2 ug/L respectively)
- R01\_100314\_SB, 10/03/2014 for zinc (9 ug/L)
- R01\_270214, 27/02/2014 for zinc (6 ug/L)
- R01\_040314, 4/03/2014 for zinc (23 ug/L)
- R01\_070314\_SB, 7/03/2014 for barium and zinc (1 and 50 ug/L respectively)

The concentrations in the rinsate samples for zinc are above the ecological screening criteria of 15 ug/L in two of these six samples. For both of these rinsate samples, soil samples taken on these dates exceeded the screening values for zinc. The concentrations of chromium (III + VI), copper, nickel and barium were all only marginally greater than the LOR and soil samples taken on these dates did not exceed the adopted screening values for these metals.

While the rinsate samples suggest there may have been some minor cross-contamination of chromium, copper, nickel and zinc, this is unlikely to materially affect the outcomes of the investigation.

Four of the trip spike samples were found to be outside the acceptable limits of 70 - 130%. All four trip spike samples were found to have a low recoverability for BTEX. The trip spike non-conformances are listed below:

- Trip Spike 1 (sample code ES 1405876002) had recoveries for BTEX ranging from 64% to 70%;
- TSP 16 (sample code ES 1404881007) had recoveries for BTEX ranging from 60% to 68%;
- Trip Spike 1 (sample code ES 1405740005) had recoveries for BTEX ranging from 65% to 68%
- TSP 1 (sample code ES 1405360014) had a recovery for Benzene of 50%

The slightly low recoverabilities on these spikes are potentially indicative of a loss of volatiles during the trip. None of the soil samples sent with these spikes were found to have concentrations of BTEX above the LOR. PID readings taken from these samples did not indicate the presence of volatile hydrocarbons. These minor non-conformances are not considered to affect the outcome of the interpretation of this data.

Table F2 Laboratory QA/QC Assessment

QA/QC Criterion	Comments
Appropriate methodologies used for sample analyses	<p>The primary laboratory used for the investigation was NATA accredited ALS, NATA Registration No. 825. The secondary laboratory used for the investigation was NATA accredited Envirolab, NATA Registration No 2901. All laboratory reports were NATA stamped and signed by a NATA signatory. All analytical methodologies were considered appropriate for the identified contaminants of potential concern in the matrix.</p> <p>Statistical data presented in the laboratory QA/QC report was considered adequate in demonstrating the precision and accuracy of the methods used to analyse field samples.</p>
Appropriate practical quantitation limits (LORs)	<p>LORs for each analyte are presented in the laboratory reports. All sample results were reported with LORs below the site assessment criteria with the exception of a small number of volatile organic compounds in groundwater (vinyl chloride, chloromethane, bromomethane, 1,2-Dichloroethane, hexachlorobutadiene, 1,2,3-trichlorobenzene and 1,2-dibromomethane), PAH compounds (Benzo(a) pyrene and Carcinogenic PAHs (as BaP TEQ) and PAHs in sediments (Acenaphthene, Acenaphthylene Anthracene, Anthracene, Benzo(a) pyrene, Naphthalene, Chrysene, Dibenz(a,h)anthracene, Fluoranthene, Fluorene, Pyrene, Phenanthrene).</p>
Laboratory QA/QC plan	<p>Copies of signed chain of custody forms were returned by the laboratory.</p> <p>Samples were received and analysed within specified laboratory holding times with the exception of holding time exceedances for mercury in 7 samples from the VO AEC. These samples were re-analysed for dissolved metals as they had previously been erroneously analysed for total metals. Whilst this occurred within the holding time for all other metals, the holding time for mercury is 28 days and was therefore exceeded by 5 days. There were also minor exceedances for vinyl chloride and styrene as listed in Table F14. These samples were from three sample batches, ES14065900, ES14069070 and ES14070230 and the holding times were exceeded by 0.375 – 2.375 days for both compounds. These holding time non-conformances are relatively minor are not considered to have material effects on the investigation. This information was documented on the laboratory reports.</p> <p>The analytical methods used were NATA approved as documented on the laboratory reports.</p> <p>Laboratory quality control samples included laboratory control samples, internal duplicates, matrix spikes and method blanks. The types of QA/QC samples analysed by the laboratory for the documented samples were considered sufficient to assess the precision and accuracy of the laboratory methods used.</p> <p>The statistical data presented in the laboratory QA/QC report was considered adequate in demonstrating the precision and accuracy of the methods used to analyse field samples. Minor exceedances of the acceptance criteria were noted, as presented in <i>Table F10 Series to Table F13 Series</i>.</p>

Table F3 Overall Sampling and Analysis Methodology Assessment

Field Considerations	Laboratory Considerations
<i>Precision Requirements</i>	
The investigation was conducted following ERM SOPs and any variations from these procedures were documented.	Analysis of the following were reported: laboratory and inter-laboratory duplicates; field duplicates; and laboratory prepared volatile trip spikes.
<i>Precision Comments</i>	
No significant variations from ERM SOPs were noted. Field split duplicates were generally reported within the acceptance limits of 30% RPD where one or both values were greater than 10 x LOR or 50% RPD where both values less than 10 x LOR. Minor exceedances were noted, as presented in Table F5 Series. Trip spike recoveries were within the acceptance limits of 70% to 130% RPD. Exceedances were noted, as presented in Table F9 series. Trip spike recoveries from two trip spikes were not within acceptable ranges. As discussed previously, these results are generally not considered to affect analytical results. It is noted that PID field screening results from samples collected as part of these laboratory batches, where available, correlated with results of analysis or otherwise suggested that volatiles were not likely to be present.	
<i>Accuracy Requirements</i>	
The investigation was conducted following ERM SOPs and any variations from these procedures were documented.	Analysis of the following were reported: field blanks; rinsate blanks; reagent blanks; method blanks; matrix spikes; surrogate spikes; laboratory control samples; and laboratory prepared spikes.
<i>Accuracy Comments</i>	
No significant variations from ERM SOPs were noted. Laboratory QA/QC samples were reported within the acceptance limits specified in the laboratory reports. Exceptions are presented in Table F10 Series to Table F14 Series and the laboratory reports.	
<i>Representativeness Requirements</i>	
Appropriate media were identified and sampled according to the SAQP.	All samples were analysed in general accordance with the SAQP.
<i>Representativeness Comments</i>	
No exceedances of the requirements were noted.	
<i>Comparability Requirements</i>	
The same SOPs were used during each sampling event.	Analytical methods suitable for the target media were used.
All sampling was conducted by an appropriately qualified and experienced sampler.	The LORs used to report analyte concentrations were less than the adopted investigation levels for most analytes, however exceptions were noted.
The types of samples collected were consistent.	The same laboratories were used to analyse all sample.
Results of Field Screening comparable with Lab analysis.	The same units were used to report analyte concentrations.

Field Considerations	Laboratory Considerations
	<p>Results of Lab analysis comparable with field screening results.</p> <p>Results of TPH C6-C9 comparable to BTEX etc.</p>
<i>Comparability Comments</i>	
<p>All sample results were reported with LORs below the site assessment criteria with the exception of a small number of VOCs and PAH compounds.</p>	
<i>Completeness Requirements</i>	
<p>All critical locations were sampled.</p> <p>The investigation was conducted following ERM SOPs and variations from these procedures were documented.</p> <p>All sampling was conducted by an appropriately qualified and experienced sampler.</p> <p>Documentation of field works was provided.</p>	<p>All critical samples were analysed according to SAQP.</p> <p>All analytes were analysed according to the SAQP.</p> <p>Appropriate analysis methods and LORs were used.</p> <p>Sample documentation was provided.</p> <p>Sample holding times were complied with, apart from of vinyl chloride and styrene in three sample batches, where samples were held up to two and a half days longer than the specified holding time prior to analysis.</p>
<i>Completeness Comments</i>	
<p>Holding time exceptions are presented in <i>Table F14</i> and the laboratory reports, and apply only to three sample batches. Where investigation locations were not able to be completed due to logistical issues, these were discussed in Table 3.1 in the report. A number of LORs for VOCs in groundwater and PAHs in sediment were below adopted assessment criteria and were discussed in Section 3.5.3 of the report. Given the extent of investigation successfully completed across the site, including targeting of potential sources within AECs, the variations from the SAQP were minor and are generally not considered to affect the outcomes of the investigation.</p>

\*RPDs have only been considered where a concentration is greater than 0 times the EQL.

\*\*High RPDs are in bold (Acceptable RPDs for each EQL multiplier range are: 50 (0-10 x EQL); 30 (10-20 x EQL); 30 (> 20 x EQL) )

\*\*\*Interlab Duplicates are matched on a per compound basis as methods vary between laboratories. Any methods in the row header relate to those used in the primary laboratory
